Schopenhauer as a young man

ON THE FOURFOLD ROOT OF THE PRINCIPLE OF SUFFICIENT REASON

Translated by Mme. Karl Hillebrand

On the Fourfold Root of the Principle of Sufficient Reason is Schopenhauer's doctoral dissertation, which he wrote in 1813, providing an elaboration on the classical Principle of Sufficient Reason. This theme is a powerful and controversial philosophical principle stipulating that everything must have a reason or cause. Schopenhauer revised and re-published his dissertation in 1847 and it would serve as the centrepiece for many of his later arguments in his major works.

The essay was composed shortly after the events of January 1813, following the disastrous defeat of Napoleon's Grande Armée. As survivors were arriving in Berlin, the sick and wounded quickly filled up the hospitals and the risk of an epidemic grew high. A patriotic, militaristic spirit stirred the city and most of the populace, philosophers and students included, hoped that the French yoke could be thrown off. All this rapidly became intolerable to Schopenhauer, who ultimately fled the city, retreating to an inn in the small town of Rudolstadt near Weimar. It was here, from June to November of that year, that he wrote *On the Fourfold Root of the Principle of Sufficient Reason*.

After submitting the dissertation he was awarded a PhD from the University of Jena in absentia and private publication soon followed. Scarcely more than one hundred copies were sold; the rest were remaindered and, a few years later, pulped. A copy was sent to Goethe who responded by inviting the author to his home on a regular basis, ostensibly to discuss philosophy, but in reality to recruit the young philosopher into work on his *Theory of Colours*.

Schopenhauer's epistemology, by direct admission, opens with Immanuel Kant's theory of knowledge. Schopenhauer proclaims himself a Kantian, who has appropriated his predecessor's most powerful accomplishment in epistemology, and who then claims to have merely extended and completed what Kant misapplied or had left undone.

Schopenhauer argues that Kant's chief merit lies in his distinction between the thing in itself and the phenomenal world in which it appears, i.e., the world as we represent it to ourselves. What is crucial is the realisation that what makes human experience universally possible to begin with without exception is the perceiving mind. The intellect synthesises perceptions from raw sensations to consequently abstract modified concepts built upon formed perceptions. Schopenhauer appropriates Kant's forms of sensibility (space, time, and causality) and expands them into what he calls the 'understanding'.

Thus, our understanding does not exist independent of our ability to perceive and determine relationships anchored in experience itself. Not only what we think in the abstract, but also our very perceptions are completely intellectual and subjectively determined via extraction, new formation and modified formulation.

Schopenhauer's central proposition is the main idea of his entire philosophy — "the world is my representation." The rest of his work undergoes an elaborate analysis and explanation of this sentence, which begins with his Kantian epistemology, elaborated further in his explanation of the principle of sufficient reason. This is responsible for providing adequate explanations for any 'thing,' or object that occurs in relation to a subject of knowing; of any representation possible there is always a possible question of 'why?' that one can address to it. It amounts to what Schopenhauer has done, in his view, to extend and complete what Kant began in his *Critique of Pure Reason*.

The German philosopher Immanuel Kant (1724-1804) is considered a central figure in modern philosophy. Kant argued that the human mind creates the structure of human experience, that reason is the source of morality, that aesthetics arises from a faculty of disinterested judgment. Kant would have a major influence on the early work of Schopenhauer.

TRANSLATOR'S PREFACE.

In venturing to lay the present translation[1] before the public, I am aware of the great difficulties of my task, and indeed can hardly hope to do justice to the Author. In fact, had it not been for the considerations I am about to state, I might probably never have published what had originally been undertaken in order to acquire a clearer comprehension of these essays, rather than with a view to publicity.

The two treatises which form the contents of the present volume have so much importance for a profound and correct knowledge of Schopenhauer's philosophy, that it may even be doubted whether the translation of his chief work, "Die Welt als Wille und Vorstellung," can contribute much towards the appreciation of his system without the help at least of the "Vierfache Wurzel des Satzes vom zureichenden Grunde." Schopenhauer himself repeatedly and urgently insists upon a previous thorough knowledge of Kant's philosophy, as the basis, and of his own "Fourfold Root," as the key, to his own system, asserting that knowledge to be the indispensable condition for a right comprehension of his meaning. So far as I am aware, neither the "Fourfold Root" nor the "Will in Nature" have as yet found a translator; therefore, considering the dawning interest which has begun to make itself felt for Schopenhauer's philosophy in England and in America, and the fact that no more competent scholar has come forward to do the work, it may not seem presumptuous to suppose that this version may be acceptable to those who wish to acquire a more than superficial knowledge of this remarkable thinker, yet whose acquaintance with German does not permit them to read his works in the original.

Now although some portions of both the Essays published in the present volume have of course become antiquated, owing to the subsequent development of the empirical sciences, while others — such as, for instance, Schopenhauer's denunciation of plagiarism in the cases of Brandis and Rosas in the beginning of Physiology and Pathology[2] — can have no interest for the reader of the present day, I have nevertheless given them just as he left them and refrained from all suppression or alteration. And if, on the whole, the "Will in Nature" may be less indispensable for a right understanding of our philosopher's views than the "Fourfold Root," being merely a record of the confirmations which had been contributed during his

lifetime by the various branches of Natural Science to his doctrine, that *the thing in itself is the will*, the Second Essay has nevertheless in its own way quite as much importance as the First, and is, in a sense, its complement. For they both throw light on Schopenhauer's view of the Universe in its double aspect as Will and as Representation, each being as it were *a résumé* of the exposition of one of those aspects. My plea for uniting them in one volume, in spite of the difference of their contents and the wide lapse of time (seventeen years) which lies between them, must be, that they complete each other, and that their great weight and intrinsic value seem to point them out as peculiarly fitted to be introduced to the English thinker.

In endeavouring to convey the Author's thoughts as he expresses them, I have necessarily encountered many and great difficulties. His meaning, though always clearly expressed, is not always easy to seize, even for his countrymen; as a foreigner, therefore, I may often have failed to grasp, let alone adequately to render, that meaning. In this case besides, the responsibility for any want of perspicuity cannot be shifted by the translator on to the Author; since the consummate perfection of Schopenhauer's prose is universally recognised, even by those who reject, or at least who do not share, his views. An eminent German writer of our time has not hesitated to rank him immediately after Lessing and Göthe as the third greatest German prose-writer, and only quite recently a German professor, in a speech delivered with the intent of demolishing Schopenhauer's philosophy, was reluctantly obliged to admit that his works would remain on account of their literary value. Göthe himself expressed admiration for the clearness of exposition in Schopenhauer's chief work and for the beauty of his style.

The chief obstacle I have encountered in translating these Essays, did not therefore consist in the obscurity of the Author's style, nor even in the difficulty of finding appropriate terms wherewith to convey his meaning; although at times certainly the want of complete precision in our philosophical terminology made itself keenly felt and the selection was often far from easy: it lay rather in the great difference in the way of thinking and of expressing their thoughts which lies between the two nations. The regions of German and English thought are indeed separated by a gulf, which at first seems impassable, yet which must be bridged over by some means or other, if a right comprehension is to be achieved. The German writer loves to develop synthetically a single thought in a long period consisting of various members; he proceeds steadily to unravel the

seemingly tangled skein, while he keeps the reader ever on the alert, making him assist actively in the process and never letting [viii] him lose sight of the main thread. The English author, on the contrary, anxious before all things to avoid confusion and misunderstanding, and ready for this end not only to sacrifice harmony of proportion in construction, but to submit to the necessity of occasional artificial joining, usually adopts the analytical method. He prefers to divide the thread of his discourse into several smaller skeins, easier certainly to handle and thus better suiting the convenience of the English thinker, to whom long periods are trying and bewildering, and who is not always willing to wait half a page or more for the point of a sentence or the gist of a thought. Wherever it could be done without interfering seriously with the spirit of the original, I have broken up the longer periods in these essays into smaller sentences, in order to facilitate their comprehension. At times however Schopenhauer recapitulates a whole side of his view of the Universe in a single period of what seems intolerable length to the English reader: as, for instance, the *résumé* contained in the Introduction to his "Will in Nature,"[3] which could not be divided without damage to his meaning. Here therefore it did not seem advisable to sacrifice the unity and harmony of his design and to disturb both his form and his meaning, in order to minister to the reader's dislike for mental exertion; in keeping the period intact I have however endeavoured to make it as easy to comprehend as possible by the way in which the single parts are presented to the eye.

As regards the terms chosen to convey the German meaning, I can hardly hope to have succeeded in every case in adequately rendering it, still less can I expect to have satisfied my English readers. Several words of frequent occurrence and of considerable importance for the right understanding of the original, have been used at different times by different English philosophers in senses so various, that, until our philosophical terminology has by universal consent attained far greater precision than at present, it must always be difficult for the writer or translator to convey to the reader's mind precisely the same thought that was in his own. To prevent unnecessary confusion however, by leaving too much to chance, I will here briefly state those terms which give most latitude for misapprehension, explaining the sense in which I employ them and also the special meaning attached to some of them by Schopenhauer, who often differs in this from other writers. They are as follows.

(*a.*) *Anschauung* (*anschauen*, literally 'to behold') I have rendered differently, according to its double meaning in German. When used to designate the mental act by which an object is perceived, as the cause of a sensation received, it is rendered by *perception*. When used to lay stress upon *immediate*, as opposed to *abstract* representation, it is rendered by *intuition*. This last occurs however more often in the adjective form.

(*b.*) *Vorstellung* (*vorstellen*, literally 'to place before') I render by *representation* in spite of its foreign, unwelcome sound to the English ear, as being the term which nearest approaches the German meaning. The faculty of representation is defined by Schopenhauer himself as "an exceedingly complicated physiological process in the brain of an animal, the result of which is the consciousness of a *picture* there."

(*c.*) *Auffassung* (*auffassen*, literally 'to catch up') has so many shades of meaning in German that it has to be translated in many different ways according to the relation in which it stands in the context. It signifies *apprehension*, *comprehension*, *perception*, *viewing* and *grasping*.

(*d.*) *Wahrnehmung* (*wahrnehmen*, from *wahr*, true, and *nehmen*, to take), is translated by *apprehension* or *perception*, according to the degree of consciousness which accompanies it.

But the two words which have proved most difficult to translate, have been *Vernehmen* and *Willkühr*.

(*e.*) *Vernehmen* means, to distinguish by the sense of hearing. This word conveys a shade of thought which it is almost impossible to render in English, because we have no word by which to distinguish, from mere sensuous hearing, a sort of hearing which implies more than hearing and less than comprehension. The French *entendre* comes nearer to it than our *hearing*, but implies more comprehension than *vernehmen*.

(*f.*) As to *Willkühr* (*arbitrium*, literally '*will-choice*'), after a great deal of consideration I have chosen (*relative*) *free-will* as the nearest approach to the German sense, or at any rate, to that in which Schopenhauer uses it. *Willkühr* means in fact what is commonly understood as free-will; *i.e.* will with power of choice, will determined by motives and unimpeded by outward obstacles: *arbitrium* as opposed to *voluntas*: conscious will as opposed to blind impulse. This relative free-will however is quite distinct from *absolute free-will* (*liberum arbitrium indifferentiæ*) in a metaphysical sense, *i.e.* will in its self-dependency. When its arbitrary character is

specially emphasized, we call *Willkühr*, *caprice*, but this is not the usual meaning given to it by Schopenhauer.

Besides the meaning of these German words, I have still to define the sense in which I have used the term *idea* in this translation; for this word has greatly changed its meaning at different times and with different authors, and is even now apt to confuse and mislead. Schopenhauer has himself contributed in one way to render its signification less clear; since, in spite of his declaration in the "Fourfold Root"[4] to the effect, that he never uses the word *idea* in any other than its original (Platonic) sense, he has himself employed it to translate *Vorstellung*, in a specimen he gives of a rendering of a passage in Kant's "Prolegomena" in a letter addressed to Haywood, published in Gwinner's "Biography of Schopenhauer." This he probably did because some eminent English and French philosophers had taken the word in this sense, thinking perhaps that Kant's meaning would thus be more readily understood. As however he uses the word '*idea*' everywhere else exclusively in its original (Platonic) sense, I have preferred to avoid needless confusion by adhering to his own declaration and definition. Besides, many English writers of note have protested against any other sense being given to it, and modern German philosophers have more and more returned to the original meaning of the term.

Some readers may take exception at such expressions as *à priority*, *motivation*, *aseity*; for they are not, strictly speaking, English words. These terms however belong to Schopenhauer's own characteristic terminology, and have a distinct and clearly defined meaning; therefore they had to be retained in all cases in which they could not be evaded, in order not to interfere with the Author's intention: a necessity which the scholar will not fail to recognise, especially when I plead in my defence that fidelity and accuracy have been my sole aim in this work.

If moreover Carlyle's words, "He who imports into his own country any true delineation, any rationally spoken word on any subject, has done well," are true, I may also be absolved from censure, if I lay before the public this version of some important utterances of a great thinker, in the hope that it may be an assistance in, and an incitement to, a deeper study of all Schopenhauer's works.

The Translator.

Ναὶ μὰ τὸν ἁμετέρᾳ ψυχᾷ παραδόντα *τετρακτύν*,

Παγὰν ἀενάου φύσεως *ῥιζώματ’* ἔχουσαν.

THE AUTHOR'S PREFACE TO THE SECOND EDITION.

This treatise on Elementary Philosophy, which first appeared in the year 1813, when it procured for me the degree of doctor, afterwards became the substructure for the whole of my system. It cannot, therefore, be allowed to remain out of print, as has been the case, without my knowledge, for the last four years.

On the other hand, to send a juvenile work like this once more into the world with all its faults and blemishes, seemed to me unjustifiable. For I am aware that the time cannot be very far off when all correction will be impossible; but with that time the period of my real influence will commence, and this period, I trust, will be a long one, for I firmly rely upon Seneca's promise: "*Etiamsi omnibus tecum viventibus silentium livor indixerit; venient qui sine offensa, sine gratia judicent.*"[5] I have done what I could, therefore, to improve this work of my youth, and, considering the brevity and uncertainty of life, I must even regard it as an especially fortunate circumstance, to have been thus permitted to correct in my sixtieth year what I had written in my twenty-sixth.

Nevertheless, while doing this, I meant to deal leniently with my younger self, and to let him discourse, nay, even speak his mind freely, wherever it was possible. But [xviii] wherever he had advanced what was incorrect or superfluous, or had even left out the best part, I have been obliged to interrupt the thread of his discourse. And this has happened often enough; so often, indeed, that some of my readers may perhaps think they hear an old man reading a young man's book aloud, while he frequently lets it drop, in order to indulge in digressions of his own on the same subject.

It is easy to see that a work thus corrected after so long an interval, could never acquire the unity and rounded completeness which only belong to such as are written in one breath. So great a difference will be found even in style and expression, that no reader of any tact can ever be in doubt whether it be the older or younger man who is speaking. For the contrast is indeed striking between the mild, unassuming tone in which the youth — who is still simple enough to believe quite seriously that for all whose pursuit is philosophy, truth, and truth alone, can have importance, and therefore that whoever promotes truth is sure of a welcome from them — propounds his arguments with confidence, and the firm, but also at times somewhat harsh

voice of the old man, who in course of time has necessarily discovered the true character and real aims of the noble company of mercenary time-servers into which he has fallen. Nay, the just reader will hardly find fault with him should he occasionally give free vent to his indignation; since we see what comes of it when people who profess to have truth for their sole aim, are always occupied in studying the purposes of their powerful superiors, and when the *e quovis ligno fit Mercurius* is extended even to the greatest philosophers, and a clumsy *charlatan*, like Hegel, is calmly classed among them? Verily German Philosophy stands before us loaded with contempt, the laughing-stock of other nations, expelled from all honest science — like the prostitute who sells herself for sordid hire to-day to one, to-morrow to another; and the brains of the present generation of *savants* are disorganised by Hegelian nonsense: incapable of reflection, coarse and bewildered, they fall a prey to the low Materialism which has crept out of the basilisk's egg. Good speed to them. I return to my subject.

My readers will thus have to get over the difference of tone in this treatise; for I could not do here what I had done in my chief work, that is, give the later additions I had made in a separate appendix. Besides, it is of no consequence that people should know what I wrote in my twenty-sixth and what in my sixtieth year; the only matter of real importance is, that those who wish to find their way through the fundamental principles of all philosophizing, to gain a firm footing and a clear insight, should in these few sheets receive a little volume by which they may learn something substantial, solid, and true: and this, I hope, will be the case. From the expansion now given to some portions, it has even grown into a compendious theory of the entire faculty of knowing, and this theory, by limiting itself strictly to the research of the Principle of Sufficient Reason, shows the matter from a new and peculiar side; but then it finds its completion in the First Book of "The World as Will and Representation," together with those chapters of the Second Volume which refer to it, and also in my Critique of Kantian Philosophy.

Arthur Schopenhauer.

Frankfurt am Main,
September, 1847.

EDITOR'S PREFACE TO THE THIRD EDITION.

In the present volume I lay before the public the Third Edition of the "Fourfold Root," including the emendations and additions left by Schopenhauer in his own interleaved copy. I have already had occasion elsewhere to relate that he left copies of all his works thus interleaved, and that he was wont to jot down on these fly-leaves any corrections and additions he might intend inserting in future editions.

Schopenhauer himself prepared for the press all that has been added in the present edition, for he has indicated, by signs in the original context corresponding to other similar signs in the MS. passages, the places where he wished his additions to be inserted. All that was left for me to do, was to give in extended form a few citations he had purposed adding.

No essential corrections and additions, such as might modify the fundamental thoughts of the work, will be found in this new edition, which simply contains corrections, amplifications, and corroborations, many of them interesting and important. Let me take only a single instance: § 21, on the "Intellectual Nature of Empirical Perception." As Schopenhauer attached great importance to his proof of the *intellectual nature* of perception, nay, believed he had made a new discovery by it, he also worked out with special predilection all that tended to support, confirm, and strengthen it. Thus we find him in this § 21 quoting an interesting fact he had himself observed in 1815; then the instances of Caspar Hauser and others (taken from Franz's book, "The Eye," &c. &c.); and again the case of Joseph Kleinhaus, the blind sculptor; and finally, the physiological confirmations he has found in Flourens' "De la vie et de l'intelligence des Animaux." An observation, too, concerning the value of Arithmetic for the comprehension of physical processes, which is inserted into this same paragraph, will be found very remarkable, and may be particularly recommended to those who are inclined to set too high a value on calculation.

Many interesting and important additions will be found in the other paragraphs also.

One thing I could have wished to see left out of this Third Edition: his effusions against the "professors of philosophy." In a conversation with Schopenhauer in the year 1847, when he told me how he intended to

“chastise the professors of philosophy,”[6] I expressed my dissent on this point; for even in the Second Edition these passages had interrupted the measured progress of objective inquiry. At that time, however, he was not to be persuaded to strike them out; so they were left to be again included in this Third Edition, where the reader will accordingly once more find them, although times have changed since then.

Upon another point, more nearly touching the real issue, I had a controversy with Schopenhauer in the year 1852. In arguing against Fichte’s derivation of the *Non-Ego* from the *Ego* in his chief work,[7] he had said: —

[xxii] “Just as if Kant had never existed, the Principle of Sufficient Reason still remains with Fichte what it was with all the Schoolmen, an *æterna veritas*: that is to say, just as the Gods of the ancients were still ruled over by eternal Destiny, so was the God of the Schoolmen still ruled over by these *æterna veritates*, *i.e.*, by the metaphysical, mathematical, and metalogical truths, and even, according to some, by the validity of the moral law. These *veritates* alone were unconditioned by anything, and God, as well as the world, existed through their necessity. Thus with Fichte the *Ego*, according to the Principle of Sufficient Reason, is the reason of the world or of the *Non-Ego*, of the Object, which is the product or result of the *Ego* itself. He took good care, therefore, neither to examine nor to check the Principle of Sufficient Reason any farther. But if I had to indicate the particular form of this principle by which Fichte was guided in making the *Ego* spin the *Non-Ego* out of itself, as the spider its web, I should point to the Principle of the Sufficient Reason of Being in Space; for nothing but a reference to this principle gives any sort of sense or meaning to his laboured deductions of the way in which the *Ego* produces and manufactures the *Non-Ego* out of itself, which form the contents of the most senseless and — simply on this account — most tiresome book ever written. The only interest this Fichteian philosophy has for us at all — otherwise it would not be worth mentioning — lies in its being the tardy appearance of the real antithesis to ancient Materialism, which was the most consistent starting from the Object, just as Fichte’s philosophy was the most consistent starting from the Subject. As Materialism overlooked the fact, that with the simplest Object it forthwith posited the Subject also; so Fichte not only overlooked the fact, that with the Subject (whatever name he might choose to give it) he had already posited the Object also, because no Subject can be thought [xxiii] without it; he likewise overlooked the fact, that all derivation *à*

priori, nay, all demonstration whatsoever, rests upon a necessity, and that all necessity itself rests entirely and exclusively on the Principle of Sufficient Reason, because to be necessary, and to result from a given reason, are convertible terms; that the Principle of Sufficient Reason is still nothing but the common form of the Object as such: therefore that it always presupposes the Object and does not, as valid before and independently of it, first introduce it, and cannot make the Object arise in conformity with its own legislation. Thus this starting from the Object and the above-mentioned starting from the Subject have in common, that both presuppose what they pretend to derive: *i.e.*, the necessary correlate of their starting-point."

This last assertion "that the Principle of Sufficient Reason *already presupposes the Object*, but does not, as valid before and independently of it, first introduce it, and cannot make the Object arise in conformity with its own legislation," seemed to me so far to clash with the proof given by Schopenhauer in § 21 of the "Fourfold Root," as, according to the latter, it is *the function of the Subject's understanding* which primarily creates the *objective* world out of the subjective feelings of the sensuous organs by the application of the Principle of Sufficient Reason; so that all that is Object, as such, after all comes into being only in conformity with the Principle of Sufficient Reason, consequently that this principle cannot, as Schopenhauer asserted in his polemic against Fichte, already presuppose the Object. In 1852, therefore, I wrote as follows to Schopenhauer: —

"In your arguments against Fichte, where you say that the Principle of Sufficient Reason already presupposes the Object, and cannot, as valid before and independently of it, first introduce it, the objection occurred to me anew, that in your "Fourfold Root" you had made the Object of perception [xxiv] first come into being through the application of the Principle of Sufficient Reason, and that you yourself, therefore, derive the Object from the Subject, as, for instance, p. 73 of the "Fourfold Root" (2nd edition). How then can you maintain against Fichte that the Object is always pre-supposed by the Subject? I know of no way of solving this difficulty but the following: The Subject only presupposes in the Object what belongs to the thing in itself, what is inscrutable; but it creates itself the *representation* of the Object, *i.e.* that by which the thing in itself becomes *phenomenon*. For instance, when I see a tree, my Subject assumes the thing in itself of that tree; whereas the *representation* of it conversely

presupposes the operation of my Subject, the transition from the effect (in my eye) to its cause."

To this Schopenhauer replied as follows on the 12th of July, 1852: —

"Your answers (to the objection in question) are not the right ones. Here there cannot yet be a question of the thing in itself, and the distinction between representation and object is inadmissible: the world is representation. The matter stands rather as follows — Fichte's derivation of the *Non-Ego* from the *Ego*, is quite abstract: — A = A, *ergo*, I = I, and so forth. Taken in an abstract sense, the Object is at once posited with the Subject. For to be Subject means, to know; and to know means, to have representations. Object and representation are one and the same thing. In the "Fourfold Root," therefore, I have divided all objects or representations into four classes, within which the Principle of Sufficient Reason always reigns, though in each class under a different form; nevertheless, the Principle of Sufficient Reason always presupposes the class itself, and indeed, properly speaking, they coincide.[8] Now, in reality, the existence of the Subject of knowing is not an abstract existence. The Subject does not exist for itself and independently, as if it had dropped from the sky; it appears as the instrument of some individual phenomenon of the Will (animal, human being), whose purposes it is destined to serve, and which thereby now receives a consciousness, on the one hand, of itself, on the other hand, of everything else. The question next arises, as to how or out of what *elements* the representation of the outer world is brought about within this consciousness. This I have already answered in my "Theory of Colours" and also in my chief work,[9] but most thoroughly and exhaustively of all in the Second Edition of the "Fourfold Root," § 21, where it is shown, that all those elements are of *subjective* origin; wherefore attention is especially drawn to the great difference between all this and Fichte's humbug. For the whole of my exposition is but the full carrying out of Kant's Transcendental Idealism."[10]

I have thought it advisable to give this passage of his letter, as being relevant to the matter in question. As to the division in chapters and paragraphs, it is the same in this new edition as in the last. By comparing each single [xxvi] paragraph of the second with the same paragraph of the present edition, it will be easy to find out what has been newly added. In conclusion, however, I will still add a short list of the principal passages which are new.

LIST OF ADDITIONS TO THE THIRD EDITION.

§ 8, p. 13, the passages from “*Notandum*,” &c., to “*Ex necessitate*,” and p. 14, from “*Zunächst adoptirt*” down to the end of the page (English version, p. 14, “*Not.*,” &c., to “*Ex nec.*”; p. 15, from “First he adopts” down to the end of the paragraph, p. 16, “*est* causa sui”), in confirmation of his assertion that Spinoza had interchanged and confounded the relation between reason of knowledge and consequent, with that between cause and effect.

§ 9, p. 17, from “*er proklamirt*” down to “*gewusst haben wird*.” (E. v., § 9, p. 19, from “He proclaims it” down to “by others before.”)

§ 20, p. 42, in speaking of *reciprocity* (*Wechselwirkung*), from the words “*Ja, wo einem Schreiber*” down to “*ins Bodenlose gerathen sei*.” (E. v., § 20, p. 45, from “Nay, it is precisely” down to “his depth.”)

§ 21, p. 61, the words at the bottom, “*und räumlich konstruirt*,” down to p. 62, “*Data erhält*,” together with the quotation concerning the blind sculptor, J. Kleinhaus. (E. v., § 21, p. 67, the words “and constructs in Space” down to “of the Understanding,”) and the note.

§ 21, pp. 67-68, from “*Ein specieller und interessanter Beleg*” down to “*albernes Zeug dazu*.” (E. v., § 21, p. 73, “I will here add” down to p. 74, “followed by twaddle.”)

§ 21, p. 73, *sq.*, the instances of Caspar Hauser, &c., from Franz, “The Eye,” &c., and the physiological corroborations from Flourens, “*De la vie et de l’intelligence*,” &c. (E. v., p. 80, and following.)

[xxvii] § 21, p. 77, the parenthesis on the value of calculation. (E. v., p. 83, “All comprehension,” &c.)

§ 21, p. 83, the words “*da ferner Substanz*” down to “*das Wirken* in concreto.” (E. v., § 21, p. 90, “Substance and Matter” down to “*in concreto*.”)

§ 29, p. 105, the words “*im Lateinischen*” down to “*erkannte*.” (E. v., § 29, p. 116, from “In Latin” down to “κατ’ ἐξοχήν.”)

§ 34, p. 116, the words “*Ueberall ist*” down to “*Praxis und Theorie*.” (E. v., § 34, p. 128, the words “Reasonable or Rational” down to “theory and practice.”)

§ 34, p. 121, the verses from Göthe's "West-Östlicher Divan."

§ 34, p. 125, *Anmerkung*, the words "*Auch ist Brahma*" down to "*die erstere*," and p. 126, the quotation from I. J. Schmidt's "Forschungen." (E. v., § 34, p. 138, note, "Brahma is also" down to "first of these.")

§ 34, p. 127, the words from "*Aber der naive*" down to "*judaisirten gouverneurs*" (E. v., § 34, p. 150, sentence beginning "But the artless" down to "infancy," and the Greek quotation from Plutarch in the note.)

§ 34, p. 128, the words from "*Ganz übereinstimmend*" down to "*überflüssige sein soll*." (E. v., p. 151, from "J. F. Davis" down to "superfluous.")

§ 45, p. 147, the words "*Eben daher kommt es*" down to "*sich erhält*." (E. v., § 45, p. 163, "It is just for this reason too" down to "their possession.")

§ 45, p. 149, the words "*Man suche Das*," &c., down to "*gelesen haben*." (E. v., § 45, p. 164, from "We should" down to "read in books.")

§ 49, p. 154, the words "*Der bei den Philosophastern*," down to "*zu kontroliren sind*." (E. v., § 49, p. 169, from the words "The conception of our," &c., down to "by perception.")

§ 50, p. 156, the words "*Denn der Satz vom Grunde*" [xxviii] down to "*nur sich selbst nicht*." (E. v., § 50, p. 172, from "For the Principle of Sufficient Reason," &c., down to "everything else.")

§ 52, p. 158, the words "*Der allgemeine Sinn des Satzes vom Grunde*," down to "*der Kosmologische Beweis ist*." (E. v., § 52, p. 173, from "The general meaning" down to "the Cosmological Proof.")

Julius Frauenstädt.
Berlin, *August, 1864*.

EDITOR'S PREFACE TO THE FOURTH EDITION.

The present Fourth Edition is of the same content as the Third; therefore it contains the same corrections and additions which I had already inserted in the Third Edition from Schopenhauer's own interleaved copy of this work.

Julius Frauenstädt.

Berlin, *September, 1877*.

CHAPTER I. INTRODUCTION.

§ 1. *The Method.*

The divine Plato and the marvellous Kant unite their mighty voices in recommending a rule, to serve as the method of all philosophising as well as of all other science.[11] Two laws, they tell us: the law of *homogeneity* and the law of *specification*, should be equally observed, neither to the disadvantage of the other. The law of *homogeneity* directs us to collect things together into kinds by observing their resemblances and correspondences, to collect kinds again into species, species into genera, and so on, till at last we come to the highest all-comprehensive conception. Now this law, being transcendental, *i.e.* essential to our Reason, takes for granted that Nature conforms with it: an assumption which is expressed by the ancient formula, *entia præter necessitatem non esse multiplicanda*. As for the law of *specification*, Kant expresses it thus: *entium varietates non temere esse minuendas*. It requires namely, that we should clearly distinguish one from another the different genera collected under one comprehensive conception; likewise that we should not confound the higher and lower species comprised in each genus; that we should be careful not to overleap any, and never to classify inferior species, let alone individuals, immediately under the generic conception: each conception being susceptible of subdivision, and none even coming down to mere intuition. Kant teaches that both laws are transcendental, fundamental principles of our Reason, which postulate conformity of things with them *à priori*; and Plato, when he tells us that these rules were flung down from the seat of the gods with the Promethean fire, seems to express the same thought in his own way.

§ 2. *Application of the Method in the present case.*

In spite of the weight of such recommendations, I find that the second of these two laws has been far too rarely applied to a fundamental principle of all knowledge: *the Principle of Sufficient Reason*. For although this principle has been often and long ago stated in a general way, still sufficient distinction has not been made between its extremely different applications, in each of which it acquires a new meaning; its origin in various mental

faculties thus becoming evident. If we compare Kant's philosophy with all preceding systems, we perceive that, precisely in the observation of our mental faculties, many persistent errors have been caused by applying the principle of homogeneity, while the opposite principle of specification was neglected; whereas the law of specification has led to the greatest and most important results. I therefore crave permission to quote a passage from Kant, in which the application of the law of specification to the sources of our knowledge is especially recommended; for it gives countenance to my present endeavour: —

"It is of the highest importance to *isolate* various sorts of knowledge, which in kind and origin are different from others, and to take great care lest they be mixed up with those others with which, for practical purposes, they are generally united. What is done by the chemist in the analysis of substances, and by the mathematician in pure mathematics, is far more incumbent on the philosopher, in order to enable him to define clearly the part which, in the promiscuous employment of the understanding, belongs to a special kind of knowledge, as well as its peculiar value and influence."[12]

§ 3. *Utility of this Inquiry.*

Should I succeed in showing that the principle which forms the subject of the present inquiry does not issue directly from *one* primitive notion of our intellect, but rather in the first instance from *various* ones, it will then follow, that neither can the necessity it brings with it, as a firmly established *à priori* principle, be *one* and the *same* in all cases, but must, on the contrary, be as manifold as the sources of the principle itself. Whoever therefore bases a conclusion upon this principle, incurs the obligation of clearly specifying on which of its grounds of necessity he founds his conclusion and of designating that ground by a special name, such as I am about to suggest. I hope that this may be a step towards promoting greater lucidity and precision in philosophising; for I hold the extreme clearness to be attained by an accurate definition of each single expression to be indispensable to us, as a defence both against error and against intentional deception, and also as a means of securing to ourselves the permanent, unalienable possession of each newly acquired notion within the sphere of philosophy beyond the fear of losing it again on account of any misunderstanding or double meaning which might hereafter be detected. The true philosopher will indeed always seek after light and perspicuity, and

will endeavour to resemble a Swiss lake — which through its peacefulness is enabled to unite great depth with great clearness, the depth revealing itself precisely by the clearness — rather than a turbid, impetuous mountain torrent. "*La clarté est la bonne foi des philosophes*," says Vauvenargues. Pseudo-philosophers, on the contrary, use speech, not indeed to conceal their thoughts, as M. de Talleyrand has it, but rather to conceal the absence of them, and are apt to make their readers responsible for the incomprehensibility of their systems, which really proceeds from their own confused thinking. This explains why in certain writers — Schelling, for instance — the tone of instruction so often passes into that of reproach, and frequently the reader is even taken to task beforehand for his assumed inability to understand.

§ 4. *Importance of the Principle of Sufficient Reason.*

Its importance is indeed very great, since it may truly be called the basis of all science. For by *science* we understand a *system* of notions, *i.e.* a totality of connected, as opposed to a mere aggregate of disconnected, notions. But what is it that binds together the members of a system, if not the Principle of Sufficient Reason? That which distinguishes every science from a mere aggregate is precisely, that its notions are derived one from another as from their reason. So it was long ago observed by Plato: καὶ γὰρ αἱ δόξαι αἱ ἀληθεῖς οὐ πολλοῦ ἄξιαί εἰσιν, ἕως ἄν τις ἀυτὰς δήσῃ αἰτίας λογισμῷ (*etiam opiniones veræ non multi pretii sunt, donec quis illas ratiocinatione a causis ducta liget*).[13] Nearly every science, moreover, contains notions of causes from which the effects may be deduced, and likewise other notions of the necessity of conclusions from reasons, as will be seen during the course of this inquiry. Aristotle has expressed this as follows: πᾶσα ἐπιστήμη διανοητική, ἢ καὶ μετέχουσά τι διανοίας, περὶ αἰτίας καὶ ἀρχάς ἐστι (*omnis intellectualis scientia, sive aliquo modo intellectu participans, circa causas et principia est*).[14] Now, as it is this very assumption *à priori* that all things must have their reason, which authorizes us everywhere to search for the *why*, we may safely call this *why* the mother of all science.

§ 5. *The Principle itself.*

We purpose showing further on that the Principle of Sufficient Reason is an expression common to several *à priori* notions. Meanwhile, it must be

stated under some formula or other. I choose Wolf's as being the most comprehensive: *Nihil est sine ratione cur potius sit, quam non sit.* Nothing is without a reason for its being.[15]

CHAPTER II. GENERAL SURVEY OF THE MOST IMPORTANT VIEWS HITHERTO HELD CONCERNING THE PRINCIPLE OF SUFFICIENT REASON.

§ 6. *First Statement of the Principle and Distinction between Two of its Meanings.*

A more or less accurately defined, abstract expression for so fundamental a principle of all knowledge must have been found at a very early age; it would, therefore, be difficult, and besides of no great interest, to determine where it first appeared. Neither Plato nor Aristotle have formally stated it as a leading fundamental principle, although both often speak of it as a self-evident truth. Thus, with a *naïveté* which savours of the state of innocence as opposed to that of the knowledge of good and of evil, when compared with the critical researches of our own times, Plato says: ἀναγκαῖον, πάντα τὰ γιγνόμενα διά τινα αἰτίαν γίγνεσθαι· πῶς γὰρ ἂν χωρὶς τούτων γίγνοιτο;[16] (*necesse est, quæcunque fiunt, per aliquam causam fieri: quomodo enim absque ea fierent?*) and then again: πᾶν δὲ τὸ γιγνόμενον ὑπ' αἰτίου τινὸς ἐξ ἀνάγκης γίγνεσθαι· παντὶ γὰρ ἀδύνατον χωρὶς αἰτίου γένεσιν σχεῖν[17] (*quidquid gignitur, ex aliqua causa necessario gignitur: sine causa enim oriri quidquam, impossibile est*). At the end of his book "De fato," Plutarch cites the following among the chief propositions of the Stoics: μάλιστα μὲν καὶ πρῶτον εἶναι δόξειε, τὸ μηδὲν ἀναιτίως γίγνεσθαι, ἀλλὰ κατὰ προηγουμένας αἰτίας[18] (*maxime id primum esse videbitur, nihil fieri sine causa, sed omnia causis antegressis*).

In the "Analyt. post." i. 2, Aristotle states the principle of sufficient reason to a certain degree when he says: ἐπίστασθαι δὲ οἰόμεθα ἕκαστον ἁπλῶς, ὅταν τὴν τ' αἰτίαν οἰόμεθα γινώσκειν, δι' ἣν τὸ πρᾶγμα ἔστιν, ὅτι ἐκείνου αἰτία ἐστίν, καὶ μὴ ἐνδέχεσθαι τοῦτο ἄλλως εἶναι. (*Scire autem putamus unamquamque rem simpliciter, quum putamus causam cognoscere, propter quum res est, ejusque rei causam esse, nec posse eam aliter se habere.*)[19] In his "Metaphysics," moreover, he already divides causes, or rather principles, ἀρχαί, into different kinds,[20] of which he admits eight; but this division is neither profound nor precise enough. He is, nevertheless, quite right in saying, πασῶν μὲν οὖν κοινὸν τῶν ἀρχῶν, τὸ πρῶτον εἶναι,

ὅθεν ἢ ἔστιν, ἢ γίνεται, ἢ γιγνώσκεται.[21] (*Omnibus igitur principiis commune est, esse primum, unde aut est, aut fit, aut cognoscitur.*) In the following chapter he distinguishes several kinds of causes, although somewhat superficially and confusedly. In the "Analyt. post." ii. 11, he states four kinds of causes in a more satisfactory manner: αἰτίαι δὲ τέσσαρες· μία μὲν τό τι ἦν εἶναι· μία δὲ τὸ τινῶν ὄντων, ἀνάγκη τοῦτο εἶναι· ἑτέρα δὲ, ἥ τι πρῶτον ἐκίνησε· τετάρτη δὲ, τὸ τίνος ἕνεκα.[22] (*Causæ autem quatuor sunt: una quæ explicat quid res sit; altera, quam, si quædam sint, necesse est esse; tertia, quæ quid primum movit; quarta id, cujus gratia.*) Now this is the origin of the division of the *causæ* universally adopted by the Scholastic Philosophers, into *causæ materiales, formales, efficientes et finales*, as may be seen in "Suarii disputationes metaphysicæ"[23] — a real compendium of Scholasticism. Even Hobbes still quotes and explains this division.[24] It is also to be found in another passage of Aristotle, this time somewhat more clearly and fully developed ("Metaph." i. 3.) and it is again briefly noticed in the book "De somno et vigilia," c. 2. As for the vitally important distinction between *reason* and *cause*, however, Aristotle no doubt betrays something like a conception of it in the "Analyt. post." i. 13, where he shows at considerable length that knowing and proving *that* a thing exists is a very different thing from knowing and proving *why* it exists: what he represents as the latter, being knowledge of the *cause*; as the former, knowledge of the *reason*. If, however, he had quite clearly recognized the difference between them, he would never have lost sight of it, but would have adhered to it throughout his writings. Now this is not the case; for even when he endeavours to distinguish the various kinds of causes from one another, as in the passages I have mentioned above, the essential difference mooted in the chapter just alluded to, never seems to occur to him again. Besides he uses the term αἴτιον indiscriminately for every kind of cause, often indeed calling reasons of knowledge, and sometimes even the premisses of a conclusion, αἰτίας, as, for instance, in his "Metaph." iv. 18; "Rhet." ii. 2; "De plantis." p. 816 (*ed. Berol.*), but more especially "Analyt. post." i. 2, where he calls the premisses to a conclusion simply αἰτίαι τοῦ συμπεράσματος (causes of the conclusion). Now, using the same word to express two closely connected conceptions, is a sure sign that their difference has not been recognised, or at any rate not been firmly grasped; for a mere accidental homonymous designation of two

widely differing things is quite another matter. Nowhere, however, does this error appear more conspicuously than in his definition of the sophism *non causæ ut causa*, παρὰ τὸ μὴ αἴτιον ὡς αἴτιον, (reasoning from what is not cause as if it were cause), in the book "De sophisticis elenchis," c. 5. By αἴτιον he here understands absolutely nothing but the argument, the premisses, consequently a reason of knowledge; for this sophism consists in correctly proving the impossibility of something, while the proof has no bearing whatever upon the proposition in dispute, which it is nevertheless supposed to refute. Here, therefore, there is no question at all of physical causes. Still the use of the word αἴτιον has had so much weight with modern logicians, that they hold to it exclusively in their accounts of the *fallacia extra dictionem*, and explain the *fallacia non causæ ut causa* as designating a physical cause, which is not the case. Reimarus, for instance, does so, and G. E. Schultze and Fries — all indeed of whom I have any knowledge. The first work in which I find a correct definition of this sophism, is Twesten's Logic. Moreover, in all other scientific works and controversies the charge of a *fallacia non causæ ut causa* usually denotes the interpolation of a wrong cause.

Sextus Empiricus presents another forcible instance of the way in which the Ancients were wont universally to confound the logical law of the reason of knowledge with the transcendental law of cause and effect in Nature, persistently mistaking one for the other. In the 9th Book "Adversus Mathematicos," that is, the Book "Adversus Physicos," § 204, he undertakes to prove the law of causality, and says: "He who asserts that there is no cause (αἰτία), either has no cause (αἰτία) for his assertion, or has one. In the former case there is not more truth in his assertion than in its contradiction; in the latter, his assertion itself proves the existence of a cause."

By this we see that the Ancients had not yet arrived at a clear distinction between requiring a reason as the ground of a conclusion, and asking for a cause for the occurrence of a real event. As for the Scholastic Philosophers of later times, the law of causality was in their eyes an axiom above investigation: "*non inquirimus an causa sit, quia nihil est per se notius*," says Suarez.[25] At the same time they held fast to the above quoted Aristotelian classification; but, as far as I know at least, they equally failed to arrive at a clear idea of the necessary distinction of which we are here speaking.

§ 7. *Descartes.*

For we find even the excellent Descartes, who gave the first impulse to subjective reflection and thereby became the father of modern philosophy, still entangled in confusions for which it is difficult to account; and we shall soon see to what serious and deplorable consequences these confusions have led with regard to Metaphysics. In the "*Responsio ad secundas objectiones in meditationes de prima philosophia*," *axioma i.* he says: *Nulla res existit, de qua non possit quæri, quænam sit causa, cur existat. Hoc enim de ipso Deo quæri potest, non quod indigeat ulla causa ut existat, sed quia ipsa ejus naturæ immensitas est* CAUSA, SIVE RATIO, *propter quam nulla causa indiget ad existendum*. He ought to have said: The immensity of God is a logical reason from which it follows, that God needs no cause; whereas he confounds the two together and obviously has no clear consciousness of the difference between reason and cause. Properly speaking however, it is his intention which mars his insight. For here, where the law of causality demands a *cause*, he substitutes a *reason* instead of it, because the latter, unlike the former, does not immediately lead to something beyond it; and thus, by means of this very axiom, he clears the way to the *Ontological Proof* of the existence of God, which was really his invention, for Anselm had only indicated it in a general manner. Immediately after these axioms, of which I have just quoted the first, there comes a formal, quite serious statement of the Ontological Proof, which, in fact, already lies within that axiom, as the chicken does within the egg that has been long brooded over. Thus, while everything else stands in need of a cause for its existence, the *immensitas* implied in the conception of the Deity — who is introduced to us upon the ladder of the Cosmological Proof — suffices in lieu of a cause or, as the proof itself expresses it: *in conceptu entis summe perfecti existentia necessaria continetur*. This, then, is the sleight-of-hand trick, for the sake of which the confusion, familiar even to Aristotle, of the two principal meanings of the principle of sufficient reason, has been used directly *in majorem Dei gloriam*.

Considered by daylight, however, and without prejudice, this famous Ontological Proof is really a charming joke. On some occasion or other, some one excogitates a conception, composed out of all sorts of predicates, among which however he takes care to include the predicate actuality or existence, either openly stated or wrapped up for decency's sake in some

other predicate, such as *perfectio*, *immensitas*, or something of the kind. Now, it is well known, — that, from a given conception, those predicates which are essential to it — *i.e.*, without which it cannot be thought — and likewise the predicates which are essential to those predicates themselves, may be extracted by means of purely logical analyses, and consequently have *logical* truth: that is, they have their reason of knowledge in the given conception. Accordingly the predicate reality or existence is now extracted from this arbitrarily thought conception, and an object corresponding to it is forthwith presumed to have real existence independently of the conception.

"Wär' der Gedank' nicht so verwünscht gescheut,
Man wär' versucht ihn herzlich dumm zu nennen."[26]

After all, the simplest answer to such ontological demonstrations is: "All depends upon the source whence you have derived your conception: if it be taken from experience, all well and good, for in this case its object exists and needs no further proof; if, on the contrary, it has been hatched in your own *sinciput*, all its predicates are of no avail, for it is a mere phantasm." But we form an unfavourable prejudice against the pretensions of a theology which needed to have recourse to such proofs as this in order to gain a footing on the territory of philosophy, to which it is quite foreign, but on which it longs to trespass. But oh! for the prophetic wisdom of Aristotle! He had never even heard of the Ontological Proof; yet as though he could detect this piece of scholastic jugglery through the shades of coming darkness and were anxious to bar the road to it, he carefully shows[27] that defining a thing and proving its existence are two different matters, separate to all eternity; since by the one we learn *what* it is that is meant, and by the other *that* such a thing exists. Like an oracle of the future, he pronounces the sentence: τὸ δ' εἶναι οὐκ οὐσία οὐδενί· οὐ γὰρ γένος τὸ ὄν: (ESSE *autem nullius rei essentia, est, quandoquidem ens non est genus*) which means: "Existence never can belong to the essence of a thing." On the other hand, we may see how great was Herr von Schelling's veneration for the Ontological Proof in a long note, p. 152, of the 1st vol. of his "Philosophische Schriften" of 1809. We may even see in it something still more instructive, *i.e.*, how easily Germans allow sand to be thrown in their eyes by impudence and blustering swagger. But for so thoroughly pitiable a creature as Hegel, whose whole pseudo-philosophy is but a monstrous amplification of the Ontological Proof, to have undertaken its defence against Kant, is indeed an alliance of which the Ontological Proof itself

might be ashamed, however little it may in general be given to blushing. How can I be expected to speak with deference of men, who have brought philosophy into contempt?

§ 8. *Spinoza.*

Although Spinoza's philosophy mainly consists in the negation of the double dualism between God and the world and between soul and body, which his teacher, Descartes, had set up, he nevertheless remained true to his master in confounding and interchanging the relation between reason and consequence with that between cause and effect; he even endeavoured to draw from it a still greater advantage for his own metaphysics than Descartes for his, for he made this confusion the foundation of his whole Pantheism.

A conception contains *implicite* all its essential predicates, so that they may be developed out of it *explicite* by means of mere analytical judgments: the sum total of them being its definition. This definition therefore differs from the conception itself merely in form and not in content; for it consists of judgments which are all contained within that conception, and therefore have their reason in it, in as far as they show its essence. We may accordingly look upon these judgments as the consequences of that conception, considered as their reason. Now this relation between a conception and the judgments founded upon it and susceptible of being developed out of it by analysis, is precisely the relation between Spinoza's so-called God and the world, or rather between the one and only substance and its numberless accidents (*Deus, sive substantia constans infinitis attributis*[28] — *Deus, sive omnia Dei attributa*). It is therefore the relation in knowledge of the *reason* to its consequent; whereas true Theism (Spinoza's Theism is merely nominal) assumes the relation of the *cause* to its effect, in which the cause remains different and separate from the consequence, not only in the way in which we consider them, but really and essentially, therefore in themselves to all eternity. For the word God, honestly used, means a cause such as this of the world, with the addition of personality. An impersonal God is, on the contrary, a *contradictio in adjecto*. Now as nevertheless, even in the case as stated by him, Spinoza desired to retain the word God to express substance, and explicitly called this the *cause* of the world, he could find no other way to do it than by completely intermingling

the two relations, and confounding the principle of the reason of knowledge with the principle of causality. I call attention to the following passages in corroboration of this statement. *Notandum, dari necessario unius cujusque rei existentis certam aliquam* CAUSAM, *propter quam existit. Et notandum, hanc causam, propter quart aliqua res existit, vel debere contineri in ipsa natura et* DEFINITIONE *rei existentis* (*nimirum quod ad ipsius naturam pertinet existere*), *vel debere* EXTRA *ipsam dari.*[29] In the last case he means an efficient cause, as appears from what follows, whereas in the first he means a mere reason of knowledge; yet he identifies both, and by this means prepares the way for identifying God with the world, which is his intention. This is the artifice of which he always makes use, and which he has learnt from Descartes. He substitutes a cause acting from without, for a reason of knowledge lying within, a given conception. *Ex necessitate divinæ naturæ omnia, quæ sub intellectum infinitum cadere possunt, sequi debent.*[30] At the same time he calls God everywhere the cause of the world. *Quidquid existit Dei potentiam, quæ omnium rerum* CAUSA *est, exprimit.*[31] — *Deus est omnium rerum* CAUSA *immanens, non vero transiens.*[32] — *Deus non tantam est* CAUSA EFFICIENS *rerum existentiæ, sed etiam essentiæ.*[33] — *Ex data quacunque* IDEA *aliquis* EFFECTUS *necessario sequi debat.*[34] — And: *Nulla res nisi a causa externa potest destrui.*[35] — Demonstr. Definitio *cujuscunque rei, ipsius essentiam* (essence, nature, as differing from existentia, existence), *affirmat, sed non negat; sive rei essentiam ponit, sed non tollit. Dum itaque ad rem ipsam tantum, non autem ad causas externas attendimus, nihil in eadem poterimus invenire, quod ipsam possit destruere.* This means, that as no conception can contain anything which contradicts its definition, *i.e.*, the sum total of its predicates, neither can an existence contain anything which might become a cause of its destruction. This view, however, is brought to a climax in the somewhat lengthy second demonstration of the 11th Proposition, in which he confounds a cause capable of destroying or annihilating a being, with a contradiction contained in its definition and therefore destroying that definition. His need of confounding cause with reason here becomes so urgent, that he can never say *causa* or *ratio* alone, but always finds it necessary to put *ratio seu causa*. Accordingly, this occurs as many as eight times in the same page, in order to conceal the subterfuge. Descartes had done the same in the above-mentioned axiom.

Thus, properly speaking, Spinoza's Pantheism is merely the *realisation* of Descartes' Ontological Proof. First, he adopts Descartes' ontotheological proposition, to which we have alluded above, *ipsa naturæ Dei immensitas est* CAUSA SIVE RATIO, *propter quam nulla causa indiget ad existendum*, always saying *substantia* instead of *Deus* (in the beginning); and then he finishes by *substantiæ essentia necessario involvit existentiam, ergo erit substantia* CAUSA SUI.[36] Therefore the very same argument which Descartes had used to prove the existence of God, is used by Spinoza to prove the existence of the world, — which consequently needs no God. He does this still more distinctly in the 2nd Scholium to the 8th Proposition: *Quoniam ad naturam substantia pertinet existere, debet ejus definitio necessariam existentiam involvere, et consequenter ex sola ejus definitione debet ipsius existentia concludi*. But this substance is, as we know, the world. The demonstration to Proposition 24 says in the same sense: *Id, cujus natura in se considerata* (*i.e.*, in its definition) *involvit existentiam, est* CAUSA SUI.

For what Descartes had stated in an exclusively *ideal* and *subjective* sense, *i.e.*, only for us, for *cognitive purposes* — in this instance for the sake of proving the existence of God — Spinoza took in a *real* and *objective* sense, as the actual relation of God to the world. According to Descartes, the existence of God is contained in the *conception* of God, therefore it becomes an argument for his actual being: according to Spinoza, God is himself contained in the world. Thus what, with Descartes, was only reason of knowledge, becomes, with Spinoza, reason of fact. If the former, in his Ontological Proof, taught that the *existentia* of God is a consequence of the *essentia* of God, the latter turns this into *causa sui*, and boldly opens his Ethics with: *per causam sui intelligo id, cujus essentia* (conception) *involvit existentiam*, remaining deaf to Aristotle's warning cry, τὸ δ' εἶναι οὐκ οὑσία οὐδενί! Now, this is the most palpable confusion of *reason* and *cause*. And if Neo-Spinozans (Schellingites, Hegelians, &c.), with whom words are wont to pass for thoughts, often indulge in pompous, solemn admiration for this *causa sui*, for my own part I see nothing but a *contradictio in adjecto* in this same *causa sui*, a *before* that is *after*, an audacious command to us, to sever arbitrarily the eternal causal chain — something, in short, very like the proceeding of that Austrian, who finding himself unable to reach high enough to fasten the clasp on his tightly-

strapped shako, got upon a chair. The right emblem for *causa sui* is Baron Münchhausen, sinking on horseback into the water, clinging by the legs to his horse and pulling both himself and the animal out by his own pigtail, with the motto underneath: *Causa sui*.

Let us finally cast a look at the 16th proposition of the 1st book of the Ethics. Here we find Spinoza concluding from the proposition, *ex data cujuscunque rei definitione plures proprietates intellectus concludit, quæ revera ex eadem necessario sequuntur, that ex necessitate divinæ, naturæ* (*i.e.*, taken as a reality), *infinita infinitis modis sequi debent*: this God therefore unquestionably stands in the same relation to the world as a conception to its definition. The corollary, *Deum omnium rerum esse* CAUSAM EFFICIENTEM, is nevertheless immediately connected with it. It is impossible to carry the confusion between reason and cause farther, nor could it lead to graver consequences than here. But this shows the importance of the subject of the present treatise.

In endeavouring to add a third step to the climax in question, Herr von Schelling has contributed a small afterpiece to these errors, into which two mighty intellects of the past had fallen owing to insufficient clearness in thinking. If Descartes met the demands of the inexorable law of causality, which reduced his God to the last straits, by substituting a reason instead of the cause required, in order thus to set the matter at rest; and if Spinoza made a real cause out of this reason, *i.e.*, *causa sui*, his God thereby becoming the world itself: Schelling now made reason and consequent separate in God himself.[37] He thus gave the thing still greater consistency by elevating it to a real, substantial hypostasis of reason and consequent, and introducing us to something "in God, which is not himself, but his reason, as a primary reason, or rather reason beyond reason (abyss)." *Hoc quidem vere palmarium est.* — It is now known that Schelling had taken the whole fable from Jacob Böhme's "Full account of the terrestrial and celestial mystery;" but what appears to me to be less well known, is the source from which Jacob Böhme himself had taken it, and the real birth-place of this so-called *abyss*, wherefore I now take the liberty to mention it. It is the βυθός, i.e. *abyssus, vorago*, bottomless pit, reason beyond reason of the Valentinians (a heretical sect of the second century) which, in silence — co-essential with itself — engendered intelligence and the world, as Irenæus[38] relates in the following terms: λέγουσι γάρ τινα εἶναι ἐν ἀοράτοις, καὶ

ἀκατονομάστοις ὑψώμασι τέλειον Αἰῶνα προόντα· τοῦτον δὲ καὶ προαρχήν, καὶ προπάτορα, καὶ *βυθὸν* καλοῦσιν. — Ὑπάρχοντα δὲ αὑτὸν ἀχώρητον καὶ ἀόρατον, ἀΐδιόν τε καὶ ἀγέννητον, ἐν ἡσυχίᾳ καὶ ἠρεμίᾳ πολλῇ γεγονέναι ἐν ἀπείροις αἰῶσι χρόνων. Συνυπάρχειν δὲ αὑτῷ καὶ Ἔννοιαν, ἣν δὲ καὶ Χάριν, καὶ Σιγὴν ὀνομάζουσι· καὶ ἐννοηθῆναί ποτε ἀφ' ἑαυτοῦ προβαλέσθαι τὸν *βυθὸν* τοῦτον ἀρχὴν τῶν πάντων, καὶ καθάπερ σπέρμα τὴν προβολὴν ταύτην (ἣν προβαλέσθαι ἐνενοήθη) καθέσθαι, ὡς ἐν μήτρᾳ, τῇ συνυπαρχούσῃ, ἑαυτῷ Σιγῇ. Ταύτην δὲ, ὑποδηξαμένην τὸ σπέρμα τοῦτο, καὶ ἐγκύμονα γενομένην, ἀποκυῆσαι Νοῦν, ὅμοιόν τε καὶ ἴσον τῷ προβαλόντι, καὶ μόνον χωροῦντα τὸ μέγεθος τοῦ Πατρός. Τὸν δὲ νοῦν τοῦτον καὶ μονογενῆ καλοῦσι, καὶ ἀρχὴν τῶν πάντων.[39] (*Dicunt enim esse quendam in sublimitatibus illis, quæ nec oculis cerni, nec nominari possunt, perfectum Æonem præexistentem, quem et proarchen, et propatorem, et* Bythum *vocant. Eum autem, quum incomprehensibilis et invisibilis, sempiternus idem, et ingenitus esset, infinitis temporum seculis in summa quiete ac tranquillitate fuisse. Unâ etiam cum eo Cogitationem exstitisse, quam et Gratiam et Silentium (Sigen) nuncupant. Hunc porro* Bythum *in animum, aliquando induxisse, rerum omnium initium proferre, atque hanc, quam in animum induxerat, productionem, in Sigen (silentium) quæ unâ cum eo erat, non secus atque in vulvam demisisse. Hanc vero, suscepto hoc semine, prægnantem effectam peperisse Intellectum, parenti suo parem et æqualem, atque ita comparatum, ut solus paternæ magnitudinis capax esset. Atque hunc Intellectum et Monogenem et Patrem et principum omnium rerum appellant.*)

Somehow or other this must have come to Jacob Böhme's hearing from the History of Heresy, and Herr von Schelling must have received it from him in all faith.

§ 9. *Leibnitz.*

It was Leibnitz who first formally stated the Principle of Sufficient Reason as a main principle of all knowledge and of all science. He proclaims it very pompously in various passages of his works, giving himself great airs, as though he had been the first to invent it; yet all he finds to say about it is, that everything must have a sufficient reason for being as it is, and not otherwise: and this the world had probably found out before him. True, he

makes casual allusions to the distinction between its two chief significations, without, however, laying any particular stress upon it, or explaining it clearly anywhere else. The principal reference to it is in his “Principia Philosophiæ,” § 32, and a little more satisfactorily in the French version, entitled “Monadologie”: *En vertu du principe de la raison suffisante, nous considérons qu'aucun fait ne sauroit se trouver vrai ou existant, aucune énonciation véritable, sans qu'il y ait une raison suffisante, pourquoi il en soit ainsi et non pas autrement*.[40]

§ 10. *Wolf.*

The first writer who explicitly separated the two chief significations of our principle, and stated the difference between them in detail, was therefore Wolf. Wolf, however, does not place the principle of sufficient reason in Logic, as is now the custom, but in Ontology. True, in § 71 he urges the necessity of not confounding the principle of sufficient reason of knowing with that of cause and effect; still he does not clearly determine here wherein the difference consists. Indeed, he himself mistakes the one for the other; for he quotes instances of cause and effect in confirmation of the *principium rationis sufficientis* in this very chapter, *de ratione sufficiente*, §§ 70, 74, 75, 77, which, had he really wished to preserve that distinction, ought rather to have been quoted in the chapter *de causis* of the same work. In said chapter he again brings forward precisely similar instances, and once more enunciates the *principium cognoscendi* (§ 876), which does not certainly belong to it, having been already discussed, yet which serves to introduce the immediately following clear and definite distinction between this principle and the law of causality, §§ 881-884. *Principium*, he continues, *dicitur id, quod in se continet rationem alterius*; and he distinguishes *three* kinds: 1. Principium Fiendi (*causa*), which he defines as *ratio actualitatis alterius*, e.g., *si lapis calescit, ignis aut radii solares sunt rationes, cur calor lapidi insit*. — 2. Principium Essendi, which he defines as *ratio possibilitatis alterius; in eodem, exemplo, ratio possibilitatis, cur lapis calorem recipere possit, est in essentia seu modo compositionis lapidis*. This last conception seems to me inadmissible. If it has any meaning at all, possibility means correspondence with the general conditions of experience known to us *à priori*, as Kant has sufficiently shown. From these conditions we know, with respect to Wolf's instance of

the stone, that changes are possible as effects proceeding from causes: we know, that is, that one state can succeed another, if the former contains the conditions for the latter. In this case we find, as effect, the state of being warm in the stone; as cause, the preceding state of a limited capacity for warmth in the stone and its contact with free heat. Now, Wolf's naming the first mentioned property of this state *principium essendi*, and the second, *principium fiendi*, rests upon a delusion caused by the fact that, so far as the stone is concerned, the conditions are more lasting and can therefore wait longer for the others. That the stone should be as it is: that is, that it should be chemically so constituted as to bring with it a particular degree of specific heat, consequently a capacity for heat which stands in inverse proportion to its specific heat; that besides it should, on the other hand, come into contact with free heat, is the consequence of a whole chain of antecedent causes, all of them *principia fiendi*; but it is the coincidence of circumstances on both sides which primarily constitutes that condition, upon which, as cause, the becoming warm depends, as effect. All this leaves no room for Wolf's *principium essendi*, which I therefore do not admit, and concerning which I have here entered somewhat into detail, partly because I mean to use the word myself later on in a totally different sense; partly also, because this explanation contributes to facilitate the comprehension of the law of causality. — 3. Wolf, as we have said, distinguishes a Principium Cognoscendi, and refers also under *causa* to a *causa impulsiva, sive ratio voluntatem determinans*.

§ 11. *Philosophers between Wolf and Kant.*

Baumgarten repeats the Wolfian distinctions in his "Metaphysica," §§ 20-24, and §§ 306-313.

Reimarus, in his "Vernunftlehre,"[41] § 81, distinguishes 1. *Inward reason*, of which his explanation agrees with Wolf's *ratio essendi*, and might even be applicable to the *ratio cognoscendi*, if he did not transfer to things what only applies to conceptions; 2. *Outward reason*, i.e. *causa*. — § 120 *et seqq.*, he rightly defines the *ratio cognoscendi* as a condition of the proposition; but in an example, § 125, he nevertheless confounds it with cause.

Lambert, in the new Organon, does not mention Wolf's distinctions; he shows, however, that he recognizes a difference between reason of

knowledge and cause;[42] for he says that God is the *principium essendi* of truths, and that truths are the *principia cognoscendi* of God.

Plattner, in his Aphorisms, § 868, says: "What is called reason and conclusion within our knowledge (*principium cognoscendi, ratio — rationatum*), is in reality cause and effect (*causa efficiens — effectus*). Every cause is a reason, every effect a conclusion." He is therefore of opinion that cause and effect, in reality, correspond to the conceptions reason and consequence in our thought; that the former stand in a similar relation with respect to the latter as substance and accident, for instance, to subject and predicate, or the quality of the object to our sensation of that quality, &c. &c. I think it useless to refute this opinion, for it is easy to see that premisses and conclusion in judgments stand in an entirely different relation to one another from a knowledge of cause and effect; although in individual cases even knowledge of a cause, as such, may be the reason of a judgment which enunciates the effect.[43]

§ 12. *Hume.*

No one before this serious thinker had ever doubted what follows. First, and before all things in heaven and on earth, is the Principle of Sufficient Reason in the form of the Law of Causality. For it is a *veritas æterna*: *i.e.* it is in and by itself above Gods and Fate; whereas everything else, the understanding, for instance, which thinks that principle, and no less the whole world and whatever may be its cause — atoms, motion, a Creator, *et cætera* — is what it is only in accordance with, and by virtue of, that principle. Hume was the first to whom it occurred to inquire whence this law of causality derives its authority, and to demand its credentials. Everyone knows the result at which he arrives: that causality is nothing beyond the empirically perceived succession of things and states in Time, with which habit has made us familiar. The fallacy of this result is felt at once, nor is it difficult to refute. The merit lies in the question itself; for it became the impulse and starting-point for Kant's profound researches, and by their means led to an incomparably deeper and more thorough view of Idealism than the one which had hitherto existed, and which was chiefly Berkeley's. It led to transcendental Idealism, from which arises the conviction, that the world is as dependent upon us, as a whole, as we are dependent upon it in detail. For, by pointing out the existence of those

transcendental principles, as such, which enable us to determine *à priori*, *i.e.* before all experience, certain points concerning objects and their possibility, he proved that these things could not exist, as they present themselves to us, independently of our knowledge. The resemblance between a world such as this and a dream, is obvious.

§ 13. *Kant and his School.*

Kant's chief passage on the Principle of Sufficient Reason is in a little work entitled "On a discovery, which is to permit us to dispense with all Criticism of Pure Reason."[44] Section I., *lit.* A. Here he strongly urges the distinction between "the logical (formal) principle of cognition 'every proposition must have its reason,' and the transcendental (material) principle 'every thing must have its cause,'" in his controversy with Eberhard, who had identified them as one and the same. — I intend myself to criticize Kant's proof of the *à priori* and consequently transcendental character of the law of causality further on in a separate paragraph, after having given the only true proof.

With these precedents to guide them, the several writers on Logic belonging to Kant's school; Hofbauer, Maass, Jakob, Kiesewetter and others, have defined pretty accurately the distinction between reason and cause. Kiesewetter, more especially, gives it thus quite satisfactorily:[45] "Reason of knowledge is not to be confounded with reason of fact (cause). The Principle of Sufficient Reason belongs to Logic, that of Causality to Metaphysics.[46] The former is the fundamental principle of thought; the latter that of experience. Cause refers to real things, logical reason has only to do with representations."

Kant's adversaries urge this distinction still more strongly. G. E. Schultze[47] complains that the Principle of Sufficient Reason is confounded with that of Causality. Salomon Maimon[48] regrets that so much should be said about the sufficient reason without an explanation of what is meant by it, while he blames Kant[49] for deriving the principle of causality from the logical form of hypothetical judgments.

F. H. Jacobi[50] says, that by the confounding of the two conceptions, reason and cause, an illusion is produced, which has given rise to various false speculations; and he points out the distinction between them after his own fashion. Here, however, as is usual with him, we find a good deal more of self-complacent phrase-jugglery than of serious philosophy.

How Herr von Schelling finally distinguishes reason from cause, may be seen in his "Aphorisms introductory to the Philosophy of Nature,"[51] § 184, which open the first book of the first volume of Marcus and Schelling's "Annals of Medecine." Here we are taught that gravity is the *reason* and light the *cause* of all things. This I merely quote as a curiosity; for such random talk would not otherwise deserve a place among the opinions of serious and honest inquirers.

§ 14. *On the Proofs of the Principle.*

We have still to record various fruitless attempts which have been made to prove the Principle of Sufficient Reason, mostly without clearly defining in which sense it was taken: Wolf's, for instance, in his Ontology, § 70, repeated by Baumgarten in his "Metaphysics," § 20. It is useless to repeat and refute it here, as it obviously rests on a verbal quibble. Plattner[52] and Jakob[53] have tried other proofs, in which, however, the circle is easily detected. I purpose dealing with those of Kant further on, as I have already said. Since I hope, in the course of this treatise, to point out the different laws of our cognitive faculties, of which the principle of sufficient reason is the common expression, it will result as a matter of course, that this principle cannot be proved, and that, on the contrary, Aristotle's remark:[54] λόγον ζητοῦσι ὧν οὐκ ἔστι λόγος. ἀποδείξεως γὰρ ἀρχὴ οὐκ ἀπόδειξίς ἐστι (*rationem eorum quœrant, quorum non est ratio: demonstrationis enim principium non est demonstratio*) may be applied with equal propriety to all these proofs. For every proof is a reference to something already recognised; and if we continue requiring a proof again for this something, whatever it be, we at last arrive at certain propositions which express the forms and laws, therefore the conditions, of all thought and of all knowledge, in the application of which consequently all thought and all knowledge consists: so that certainty is nothing but correspondence with those conditions, forms, and laws, therefore their own certainty cannot again be ascertained by means of other propositions. In the fifth chapter I mean to discuss the kind of truth which belongs to propositions such as these.

To seek a proof for the Principle of Sufficient Reason, is, moreover, an especially flagrant absurdity, which shows a want of reflection. Every proof is a demonstration of the reason for a judgment which has been pronounced,

and which receives the predicate *true* in virtue precisely of that demonstration. This necessity for a reason is exactly what the Principle of Sufficient Reason expresses. Now if we require a proof of it, or, in other words, a demonstration of its reason, we thereby already assume it to be true, nay, we found our demand precisely upon that assumption, and thus we find ourselves involved in the circle of exacting a proof of our right to exact a proof.

CHAPTER III. INSUFFICIENCY OF THE OLD AND OUTLINES OF A NEW DEMONSTRATION.

§ 15. *Cases which are not comprised among the old established meanings of the Principle.*

From the summary given in the preceding chapter we gather, that two distinct applications of the principle of sufficient reason have been recognized, although very gradually, very tardily, and not without frequent relapses into error and confusion: the one being its application to judgments, which, to be true, must have a reason; the other, its application to changes in material objects, which must always have a cause. In both cases we find the principle of sufficient reason authorizing us to ask *why?* a quality which is essential to it. But are all the cases in which it authorizes us to ask *why* comprised in these two relations? If I ask: Why are the three sides of this triangle equal? the answer is: Because the three angles are so. Now, is the equality of the angles the cause of the equality of the sides? No; for here we have to do with no change, consequently with no effect which must have a cause. — Is it merely a logical reason? No; for the equality of the angle is not only a proof of the equality of the sides, it is not only the foundation of a judgment: mere conceptions alone would never suffice to explain why the sides must be equal, because the angles are so; for the conception of the equality of the sides is not contained in that of the equality of the angles. Here therefore we have no connection between conceptions and judgments, but between sides and angles. The equality of the angles is not the *direct*, but the *indirect* reason, by which we know the equality of the sides; for it is the reason why a thing is such as it is (in this case, that the sides are equal): the angles being equal, the sides must therefore be equal. Here we have a necessary connection between angles and sides, not a direct, necessary connection between two judgments. — Or again, if I ask why *infecta facta*, but never *facta infecta fieri possunt*, consequently why the past is absolutely irrevocable, the future inevitable, even this does not admit of purely logical proof by means of mere abstract conceptions, nor does it belong either to causality, which only rules *occurrences* within Time, not Time itself. The present hour hurled the preceding one into the bottomless pit of the past, not through causality, but

immediately, through its mere existence, which existence was nevertheless inevitable. It is impossible to make this comprehensible or even clearer by means of mere conceptions; we recognise it, on the contrary, quite directly and instinctively, just as we recognize the difference between right and left and all that depends upon it: for instance, that our left glove will not fit our right hand, &c. &c.

Now, as all those cases in which the principle of sufficient reason finds its application cannot therefore be reduced to logical reason and consequence and to cause and effect, the law of specification cannot have been sufficiently attended to in this classification. The law of homogeneity, however, obliges us to assume, that these cases cannot differ to infinity, but that they may be reduced to certain species. Now, before attempting this classification, it will be necessary to determine what is peculiar to the principle of sufficient reason in all cases, as its special characteristic; because the conception of the genus must always be determined before the conception of the species.

§ 16. *The Roots of the Principle of Sufficient Reason.*

Our knowing consciousness, which manifests itself as outer and inner Sensibility (or receptivity) *and as Understanding and Reason, subdivides itself into Subject and Object and contains nothing else. To be Object for the Subject and to be our representation, are the same thing. All our representations stand towards one another in a regulated connection, which may be determined* À PRIORI, *and on account of which, nothing existing separately and independently, nothing single or detached, can become an Object for us*. It is this connection which is expressed by the Principle of Sufficient Reason in its generality. Now, although, as may be gathered from what has gone before, this connection assumes different forms according to the different kinds of objects, which forms are differently expressed by the Principle of Sufficient Reason; still the connection retains what is common to all these forms, and this is expressed in a general and abstract way by our principle. The relations upon which it is founded, and which will be more closely indicated in this treatise, are what I call the Root of the Principle of Sufficient Reason. Now, on closer inspection, according to the laws of homogeneity and of specification, these relations separate into distinct species, which differ widely from each other. Their number, however, may

be reduced to *four*, according to the *four* classes into which everything that can become an object for us — that is to say, all our representations — may be divided. These classes will be stated and considered in the following four chapters.

We shall see the Principle of Sufficient Reason appear under a different form in each of them; but it will also show itself under all as the same principle and as derived from the said root, precisely because it admits of being expressed as above.

CHAPTER IV. ON THE FIRST CLASS OF OBJECTS FOR THE SUBJECT, AND THAT FORM OF THE PRINCIPLE OF SUFFICIENT REASON WHICH PREDOMINATES IN IT.

§ 17. *General Account of this Class of Objects.*

The first class of objects possible to our representative faculty, is that of *intuitive, complete, empirical* representations. They are *intuitive* as opposed to mere thoughts, *i.e.* abstract conceptions; they are *complete*, inasmuch as, according to Kant's distinction, they not only contain the formal, but also the material part of phenomena; and they are *empirical*, partly as proceeding, not from a mere connection of thoughts, but from an excitation of feeling in our sensitive organism, as their origin, to which they constantly refer for evidence as to their reality: partly also because they are linked together, according to the united laws of Space, Time and Causality, in that complex without beginning or end which forms our *Empirical Reality*. As, nevertheless, according to the result of Kant's teaching, this *Empirical Reality* does not annul their *Transcendental Ideality*, we shall consider them here, where we have only to do with the formal elements of knowledge, merely as representations.

§ 18. *Outline of a Transcendental Analysis of Empirical Reality.*

The forms of these representations are those of the inner and outer sense; namely, *Time* and *Space*. But these are only *perceptible* when *filled*. Their *perceptibility* is *Matter*, to which I shall return further on, and again in § 21. *If Time were the only form* of these representations, there could be no *coexistence*, therefore nothing *permanent* and no *duration*. For *Time* is only perceived when filled, and its course is only perceived by the *changes* which take place in that which fills it. The *permanence* of an object is therefore only recognized by contrast with the *changes* going on in other objects *coexistent* with it. But the representation of *coexistence* is impossible in Time alone; it depends, for its completion, upon the representation of *Space*; because, in mere Time, all things *follow one another*, and in mere Space all things are *side by side*; it is accordingly only

by the combination of Time and Space that the representation of coexistence arises.

On the other hand, were Space the sole form of this class of representations, there would be no *change*; for change or alteration is *succession* of states, and *succession* is only possible in *Time*. We may therefore define Time as the possibility of opposite states in one and the same thing.

Thus we see, that although infinite divisibility and infinite extension are common to both Time and Space, these two forms of empirical representations differ fundamentally, inasmuch as what is essential to the *one* is without any meaning at all for the *other*: juxtaposition having no meaning in Time, succession no meaning in Space. The empirical representations which belong to the orderly complex of reality, appear notwithstanding in both forms together; nay, the *intimate union* of both is the condition of reality which, in a sense, grows out of them, as a product grows out of its factors. Now it is the Understanding which, by means of its own peculiar function, brings about this *union* and connects these heterogeneous forms in such a manner, that *empirical reality* — albeit only for that Understanding — arises out of their mutual interpenetration, and arises as a collective representation, forming a complex, held together by the forms of the principle of sufficient reason, but whose limits are problematical. Each single representation belonging to this class is a part of this complex, each one taking its place in it according to laws known to us *à priori*; in it therefore countless objects *coexist*, because Substance, *i.e.* Matter, remains permanent in spite of the ceaseless flow of Time, and because its states change in spite of the rigid immobility of Space. In this complex, in short, the whole objective, real world exists for us. The reader who may be interested in this, will find the present rough sketch of the analysis of empirical reality further worked out in § 4 of the first volume of "Die Welt als Wille und Vorstellung,"[55] where a closer explanation is given of the way in which the Understanding effects this union and thus creates for itself the empirical world. He will also find a very important help in the table, "*Prædicabilia à priori* of Time, Space, and Matter," which is added to the fourth chapter of the second volume of the same work, and which I recommend to his attention, as it especially shows how the contrasts of Time and Space are equally balanced in Matter, as their product, under the form of Causality.

We shall now proceed to give a detailed exposition of that function of the Understanding which is the basis of empirical reality; only we must first, by a few incidental explanations, remove the more immediate objections which the fundamental idealism of the view I have adopted might encounter.

§ 19. *Immediate Presence of Representations.*

Now as, notwithstanding this union through the Understanding of the forms of the inner and outer sense in representing Matter and with it a permanent outer world, all *immediate* knowledge is nevertheless acquired by the Subject through the *inner* sense alone — the outer sense being again Object for the inner, which in its turn perceives the perceptions of the outer — and as therefore, with respect to the *immediate presence* of representations in its consciousness, the Subject remains under the rule of *Time* alone, as the form of the *inner sense*:[56] it follows, that only one representation can be present to it (the Subject) at the same time, although that one may be very complicated. When we speak of representations as *immediately present*, we mean, that they are not only known in the union of Time and Space effected by the Understanding — an intuitive faculty, as we shall soon see — through which the collective representation of empirical reality arises, but that they are known in mere Time alone, as representations of the inner sense, and just at the neutral point at which its two currents separate, called the *present*. The necessary condition mentioned in the preceding paragraph for the immediate presence of a representation of this class, is its causal action upon our senses and consequently upon our organism, which itself belongs to this class of objects, and is therefore subject to the causal law which predominates in it and which we are now about to examine. Now as therefore, on the one hand, according to the laws of the inner and outer world, the Subject cannot stop short at that one representation; but as, on the other hand, there is no coexistence in Time alone: that single representation must always vanish and be superseded by others, in virtue of a law which we cannot determine *à priori*, but which depends upon circumstances soon to be mentioned. It is moreover a well-known fact, that the imagination and dreams reproduce the immediate presence of representations; the investigation of that fact, however, belongs to empirical Psychology. Now as, notwithstanding the transitory, isolated nature of our

representations with respect to their immediate presence in our consciousness, the Subject nevertheless retains the representation of an all-comprehensive complex of reality, as described above, by means of the function of the Understanding; representations have, on the strength of this antithesis, been viewed, as something quite different when considered as belonging to that complex than when considered with reference to their immediate presence in our consciousness. From the former point of view they were called *real things*; from the latter only, representations κατ' ἐξοχήν. This view of the matter, which is the ordinary one, is known under the name of *Realism*. On the appearance of modern philosophy, *Idealism* opposed itself to this *Realism* and has since been steadily gaining ground. Malebranche and Berkeley were its earliest representatives, and Kant enhanced it to the power of Transcendental Idealism, by which the co-existence of the Empirical Reality of things with their Transcendental Ideality becomes conceivable, and according to which Kant expresses himself as follows:[57] "*Transcendental Idealism* teaches that all phenomena are representations only, not things by themselves." And again:[58] "Space itself is nothing but mere representation, and whatever is in it must therefore be contained in that representation. There is nothing whatever in Space, except so far as it is really represented in it." Finally he says:[59] "If we take away the thinking Subject, the whole material world must vanish; because it is nothing but a phenomenon in the sensibility of our own subject and a certain class of its representations." In India, Idealism is even a doctrine of popular religion, not only of Brahminism, but of Buddhism; in Europe alone is it a paradox, in consequence of the essentially and unavoidably realistic principle of Judaism. But Realism quite overlooks the fact, that the so-called existence of these real things is *absolutely nothing but their being represented* (*ein Vorgestellt-werden*), or — if it be insisted, that only the immediate presence in the consciousness of the Subject can be called being represented κατ' ἐντελέχειαν — it is even only a possibility of being represented κατὰ δύναμιν. The realist forgets that the Object ceases to be Object apart from its reference to the Subject, and that if we take away that reference, or think it away, we at once do away with all objective existence. Leibnitz, while he clearly felt the Subject to be the necessary condition for the Object, was nevertheless unable to get rid of the thought that objects exist by themselves and independently of all reference whatsoever to the Subject, *i.e.* independently of being represented. He

therefore assumed in the first place a world of objects exactly like the world of representations and running parallel with it, having no direct, but only an outward connection with it by means of a *harmonia præstabilita*; — obviously the most superfluous thing possible, for it never comes within perception, and the precisely similar world of representations which does come within perception, goes its own way regardless of it. When, however, he wanted to determine more closely the essence of these things existing objectively in themselves, he found himself obliged to declare the Objects in themselves to be Subjects (*monades*), and by doing so he furnished the most striking proof of the inability of our consciousness, in as far as it is merely cognitive, to find within the limits of the intellect — *i.e.* of the apparatus by means of which we represent the world — anything beyond Subject and Object; the representer and the represented. Therefore, if we abstract from the objectivity of an Object, or in other words, from its being represented (*Vorgestellt-werden*), if we annul it in its quality as an Object, yet still wish to retain something, we can meet with nothing but *the Subject*. Conversely, if we desire to abstract from the subjectivity of the Subject, yet to have something over, the contrary takes place, and this leads to Materialism.

Spinoza, who never thoroughly sifted the matter, and never therefore acquired a clear notion of it, nevertheless quite understood the necessary correlation between Subject and Object as so essential, that they are inconceivable without it; consequently he defined it as an identity in the Substance (which alone exists) of that which knows, with that which has extension.

Observation. — With reference to the chief argument of this paragraph, I take the opportunity to remark that if, in the course of this treatise, for the sake of brevity and in order to be more easily understood, I at any time use the term *real objects*, I mean by it nothing but the intuitive representations that are united to form the complex of empirical reality, which reality in itself always remains ideal.

§ 20. *Principle of Sufficient Reason of Becoming.*

In the Class of Objects for the Subject just described, the principle of sufficient reason figures as the *Law of Causality*, and, as such, I call it the *Principle of Sufficient Reason of Becoming, principium rationis sufficientis*

fiendi. By it, all objects presenting themselves within the entire range of our representation are linked together, as far as the appearance and disappearance of their states is concerned, *i.e.* in the movement of the current of Time, to form the complex of empirical reality. The law of causality is as follows. When one or several real objects pass into any new state, some other state must have preceded this one, upon which the new state regularly follows, *i.e.* as often as that preceding one occurs. This sort of following we call *resulting*; the first of the states being named a *cause*, the second an *effect*. When a substance takes fire, for instance, this state of ignition must have been preceded by a state, 1°, of affinity to oxygen; 2°, of contact with oxygen; 3°, of a given temperature. Now, as ignition must necessarily follow immediately upon this state, and as it has only just taken place, that state cannot always have been there, but must, on the contrary, have only just supervened. This supervening is called a *change*. It is on this account that the law of causality stands in exclusive relation to *changes* and has to do with them alone. Every effect, at the time it takes place, is a *change* and, precisely by not having occurred sooner, infallibly indicates some other *change* by which it has been preceded. That other *change* takes the name of *cause*, when referred to the following one — of *effect*, when referred to a third necessarily preceding *change*. This is the chain of causality. It is necessarily without a beginning. By it, each supervening state must have resulted from a preceding change: in the case just mentioned, for instance, from the substance being brought into contact with free heat, from which necessarily resulted the heightened temperature; this contact again depended upon a preceding change, for instance the sun's rays falling upon a burning-glass; this again upon the removal of a cloud from before the sun; this upon the wind; the wind upon the unequal density of the atmosphere; this upon other conditions, and so forth *in infinitum*. When a state contains all the requisite conditions for bringing about a new state excepting *one, this one*, when at last it arrives, is, in a sense, rightly called the cause κατ' ἐξοχήν, inasmuch as we here have the final — in this case the decisive — change especially in view; but if we leave out this consideration, no single condition of the causal state has any advantage over the rest with reference to the determination of the causal connection in general, merely because it happens to be the last. Thus the removal of the cloud in the above example, is in so far the cause of the igniting, as it took place later than the direction

of the burning-glass towards the object; but this might have taken place after the removal of the cloud and the addition of oxygen might have occurred later still: in this respect therefore it is the accidental order of things that determines which is the cause. On closer inspection, however, we find that it is *the entire state* which is the cause of the ensuing one, so that the chronological order in which its single conditions were brought about, is in all essential respects indifferent. With reference to a given case therefore, the last occurring condition of a state may be called the cause κατ' ἐξοχήν, because it completes the measure of the necessary conditions, and its appearance thus becomes the decisive change. For purposes of general consideration, however, it is only the *entire* state which, by bringing about its successor, can be regarded as the cause. The single requisites which, added together, complete and constitute the cause may be called causal elements (*ursächliche Momente*) or even *conditions*, and into these accordingly the cause may be subdivided. On the other hand, it is quite wrong to call the objects themselves causes, instead of the states: some would, for instance, call the burning-glass in the above example the cause of the ignition; while others, again, would call the cloud the cause; others the sun or the oxygen, and so on arbitrarily and without order. But it is absurd to call an object the cause of another object; first of all, because objects not only contain form and quality, but *Matter* also, which has neither beginning or end; secondly, because the law of causality refers exclusively to *changes*, *i.e.* to the entrance and exit of states in Time, wherein it regulates that special relation, in reference to which the earlier state is called *cause*, the later *effect*, and the necessary connection between both, the *resulting* of the one from the other.

I here refer the thoughtful reader to the explanations I have given in my chief work.[60] For it is of the highest importance that our conception of the true and proper meaning of the law of causality and the sphere of its validity should be perfectly clear and definite: before all things, that we should recognize, that this law refers solely and exclusively to *changes* of material states and to nothing else whatever; consequently, that it ought not to be brought in when *these* are not in question. The law of causality is the regulator of the *changes* undergone in Time by objects of our outer *experience*; but these objects are all material. Each change can only be brought about by another having preceded it, which is determined by a rule,

and then the new change takes place as being necessarily induced by the preceding one. This necessity is the causal nexus.

However simple therefore the law of causality is, we nevertheless find it expressed quite differently in all philosophical manuals, from the earliest down to the latest ages: namely, in a broader, more abstract, therefore less definite way. We are, for instance, informed, now, that it is that by which something else comes into being; now, that it is what produces another thing or gives it reality, &c. &c. Wolf says: *Causa est principium, a quo existentia, sive actualitas, entis alterius dependet*; whereas it is obvious that in causality we have only to do with changes in the form of uncreated, indestructible Matter, and that a springing into existence of what did not previously exist is an impossibility. Want of clearness of thought may, no doubt, in most cases have led to these views of the causal relation; but surely sometimes an *arrière-pensée* lurks in the background — a theological intention coqueting with the Cosmological Proof, for whose sake it is ready to falsify even transcendental, *à priori* truths, the mother's milk of human understanding. We find the clearest instance of this in Thomas Brown's book, "On the Relation of Cause and Effect," a work of 460 pages, which, in 1835, had already reached its fourth edition, and has probably since gone through several more, and which, in spite of its wearisome, pedantic, rambling prolixity, does not handle the subject badly. Now this Englishman rightly recognises, that it is invariably with *changes* that the causal law has to do, and that every effect is accordingly a *change*. Yet, although it can hardly have escaped him, he is unwilling to admit that every cause is likewise a *change*, and that the whole process is therefore nothing but the uninterrupted nexus of *changes* succeeding one another in Time. On the contrary, he persists in clumsily calling the cause an *object* or *substance*, which precedes the change, and in tormenting himself throughout his tedious book with this entirely false expression, which spoils all his explanations, notwithstanding his own better knowledge and against his conscience, simply in order that his definition may on no account stand in the way of the Cosmological Proof, which others might hereafter state elsewhere. — But what can a truth be worth which needs devices such as these to prepare its way?

And what have our own worthy, honest German professors of philosophy been doing in behalf of their dearly beloved Cosmological Proof, since Kant dealt it the death-blow in his Critique of Pure Reason? —

they, who prize truth above everything. They were, indeed, at their wits' ends, for — as these worthies well know, though they do not say so — *causa prima* is, just as well as *causa sui*, a *contradictio in adjecto*, albeit the former expression is more generally used than the latter. It is besides usually pronounced with a very serious, not to say solemn, air; nay, many people, especially English Reverends, turn up their eyes in a truly edifying way when they impressively and emphatically mention that *contradictio in adjecto*: 'the first cause.' They know that a first cause is just as inconceivable as the point at which Space ends or the moment when Time first began. For every cause is a *change*, which necessarily obliges us to ask for the preceding change that brought it about, and so on *in infinitum, in infinitum*! Even a first state of Matter, from which, as it has ceased to be, all following states could have proceeded, is inconceivable. For if this state had in itself been the cause of the following ones, they must likewise have existed from all eternity, and the actual state existing at the present moment could not have only just now come into being. If, on the other hand, that first state only began to be causal at some given period, something or other must have *changed* it, for its inactivity to have ceased; but then something must have occurred, some change must have taken place; and this again obliges us to ask for its cause — *i.e.* a change which preceded it; and here we are once more on the causal ladder, up which we are whipped step by step, higher and higher, *in infinitum, in infinitum*! (These gentlemen will surely not have the face to talk to me of Matter itself arising out of nothing! If so, they will find corollaries at their service further on.) The causal law therefore is not so accommodating as to let itself be used like a hired cab, which we dismiss when we have reached our destination; rather does it resemble the broom brought to life by the apprentice-wizard in Göthe's poem,[61] which, when once set in motion, does not leave off running and fetching water until the old master-wizard himself stops it, which he alone has the power to do. These gentlemen, however, have no master-wizards among them. So what did they do, these noble, genuine lovers of truth, ever on the alert, of course, to proclaim the advent of real merit to the world as soon as it shows itself in their profession, who far from wishing to divert attention from the works of those who are really what *they* only seem to be, by craftily ignoring and meanly keeping them dark, are naturally foremost to acknowledge their worth — aye, surely, as surely as folly loves wisdom above everything? What did they do, I say, to help their old friend, the

sorely distressed Cosmological Proof, now at its last gasp? Oh, they hit upon a shrewd device. “Friend,” they said, “you are in sorry plight since your fatal encounter with that stubborn old man in Königsberg, and indeed your brethren, the Ontological and Physico-theological Proofs are in no better condition. Never mind, you shall not be abandoned by us (that is what we are paid for, you know); only you must alter your dress and your name — there is no help for it — for if we call you by your right name, everyone will take to his heels. Now *incognito*, on the contrary, we can take you by the arm, and once more lead you into society; only, as we have just said, it must be *incognito*! That is sure to answer! First of all, your argument must henceforth be called *The Absolute*. This has a foreign, dignified, aristocratic ring; and no one knows better than we do all that can be done with Germans by assuming airs of importance. Of course all know what the real meaning is, and pique themselves upon that knowledge. But you yourself must come forward disguised, in the form of an enthymeme. Be sure and leave behind you all those prosyllogisms and premisses, by which you used to drag us wearily up the long climax, for everyone knows how utterly useless they are. Come forward with a bold face and a self-sufficient, supercilious air, like a man of few words, and at one bound you will reach the goal. Exclaim (and we will chime in), ‘*The Absolute*, confound it! *that* must *exist*, or there would be nothing at all!’ Here, strike the table with your fist. Whence does the Absolute come? ‘What a silly question! Did not I tell you it was the Absolute?’ — That will do, forsooth! That will do! Germans are accustomed to content themselves with words instead of thoughts. Do we not train them to it from their cradle? Only look at Hegelianism! What is it but empty, hollow, nauseous twaddle! Yet how brilliant a career was that of this philosophical time-server! A few mercenary individuals had only to strike up a laudation of this stuff, and they at once found an echo to their voices in the empty hollow of a thousand numskulls — an echo which still continues to resound, and to extend — and behold! an ordinary intellect, a common impostor soon became a sublime thinker. Take heart, therefore! Besides, our friend and patron, we will also second you in other ways, for how, indeed, are we to get a living without you? So that carping old faultfinder, Kant, has been criticizing Reason, and clipping her wings, has he? Well, then, we will invent a *new* sort of Reason, such as has never been heard of — a Reason that does not think, but which has direct intuition — a Reason which sees Ideas (a high-flown word, made to mystify), sees them

bodily; or which apprehends directly that which you and others seek to prove; or, again, a Reason which has forebodings of all this — this last for the benefit of those who do not care to make large concessions, but also are satisfied with very little. Let us thus pass off early inculcated, popular conceptions for direct revelations of this new kind of Reason, *i.e.* for inspirations from above. As for that old-fashioned Reason, which criticism has criticized away, let us degrade it, call it Understanding, and send it about its business. Well, and what is to become of real, true Understanding? — What in the world have we to do with real, true Understanding? — You smile incredulously; but we know our listeners, and the *harum*, *horum* we see on the students' benches before us. Bacon of Verulam already in his time said: 'Young men learn to believe at Universities.' Of this they can learn as much as they wish from us; we have a good stock of articles of faith on hand. Should any misgivings assail you, remember that we are in Germany, where what would have been impossible in any other country, has been found possible: where a dull-witted, ignorant, pseudo-philosopher, whose ineffably hollow verbiage disorganizes peoples' brains completely and permanently, a scribbler of nonsense — I am speaking of our dearly beloved Hegel — has not only been actually proclaimed a profound thinker with impunity, and even without incurring ridicule, but is readily accepted as such: yes, indeed, for this fiction has found credence for the last thirty years, and is believed to this day! — Once therefore we have this Absolute with your help, we are quite safe, in spite of Kant and his Critique. — We may then philosophise in a lofty tone, making the Universe proceed from *the Absolute* by means of the most heterogeneous deductions, one more tiresome than the other — this, by the way, being their only point of resemblance. We can call the world the Finite, and the Absolute the Infinite — thus giving an agreeable variety to our nonsense — and talk of nothing but God, explaining how, why, wherefore, by what voluntary or involuntary process he created or brought forth the world, showing whether he be within or without it, and so forth, as if Philosophy were Theology, and as if it sought for enlightenment concerning God, not concerning the Universe!"

The Cosmological Proof, with which we here have to do, and to which the above apostrophe is addressed, consists thus, properly speaking, in the assertion, that the principle of the sufficient reason of *becoming*, or the law of causality, necessarily leads to a thought which destroys it and declares it to be null and void. For the *causa prima* (*absolutum*) can only be reached

by proceeding upwards from consequence to reason, through a series prolonged *ad libitum*; but it is impossible to stop short at the *causa prima* without at once annulling the principle of sufficient reason.

Having thus briefly and clearly shown the nullity of the Cosmological Proof, as I had in my second chapter already shown the nullity of the Ontological Proof, the sympathizing reader may perhaps expect me to do the same with respect to the Physico-theological Proof, which is a great deal more plausible. As, however, this belongs by its nature to a different department of philosophy, it would be quite out of place here. I therefore refer him to Kant's Critique of Pure Reason, as well as to his Critique of the Faculty of Judgment, where he treats this subject *ex professo*; I likewise refer him, as a complement to Kant's purely negative procedure, to my own positive one in "The Will in Nature,"[62] a work which, though small in bulk, is rich and weighty in content. As for the indifferent reader, he is free to let this and indeed all my writings pass down unread to his descendants. It matters not to me; for I am here, not for one generation only, but for many.

Now, as the law of causality is known to us *à priori*, and is therefore a transcendental law, applicable to every possible experience and consequently without exception, as will be shown in § 21; as moreover it decides, that upon a given, definite, relatively first state, a second equally definite one inevitably ensues by rule, *i.e.*, always; the relation between cause and effect is a necessary one, so that the causal law authorizes us to form hypothetical judgments, and thereby shows itself to be a form of the principle of sufficient reason, upon which principle all judgments must be founded and, as will be shown further on, all *necessity* is based.

This form of our principle I call the *principle of the sufficient reason of becoming*, because its application invariably pre-supposes a change, the entering upon a new state: consequently a becoming. One of its essential characteristics is this: that the cause always precedes the effect in Time (compare § 47), and this alone gives us the original criterion by which to distinguish which is cause and which effect, of two states linked together by the causal nexus. Conversely, in some cases, the causal nexus is known to us through former experience; but the rapidity with which the different states follow upon each other is so great, that the order in which this happens escapes our perception. We then conclude with complete certitude from causality to succession: thus, for instance, we infer that the igniting of gunpowder precedes its explosion.[63]

From this essential connection between causality and succession it follows, that the conception of reciprocity, strictly speaking, has no meaning; for it presumes the effect to be again the cause of its cause: that is, that what follows is at the same time what precedes. In a “Critique of Kantian Philosophy,” which I have added to my chief work, and to which I refer my readers,[64] I have shown at length that this favourite conception is inadmissible. It may be remarked, that authors usually have recourse to it just when their insight is becoming less clear, and this accounts for the frequency of its use. Nay, it is precisely when a writer comes to the end of his conceptions, that the word ‘*reciprocity*’ presents itself more readily than any other; it may, in fact, be looked upon as a kind of alarm-gun, denoting that the author has got out of his depth. It is also worthy of remark, that the word *Wechselwirkung*, literally reciprocal action — or, as we have preferred translating it, *reciprocity* — is only found in the German language, and that there is no precise equivalent for it in daily use in any other tongue.

From the law of causality spring two corollaries which, in virtue of this origin, are accredited as cognitions *à priori*, therefore as unquestionable and without exception. They are, *the law of inertia* and that *of permanence of substance*. The first of these laws avers, that every state in which a body can possibly be — consequently that of repose as well as that of any kind of movement — must last for ever without change, diminution, or augmentation, unless some cause supervenes to alter or annul it. But the other law, by which the eternity of Matter is affirmed, results from the fact, that the law of causality is exclusively applicable to *states* of bodies, such as repose, movement, form, and quality, since it presides over their temporal passing in or out of being; but that it is by no means applicable to the existence of *that which endures* these states, and is called *Substance*, in order precisely to express its exemption from all arising and perishing. ‘*Substance is permanent*’ means, that it can neither pass into, nor out of being: so that its quantity existing in the universe can neither be increased nor diminished. That we know this *à priori*, is proved by the consciousness of unassailable certainty with which, when we see a body disappear — whether it be by conjuring, by minute subdivision, by combustion, volatilisation, or indeed any process whatever — we all nevertheless firmly assume that its substance, *i.e.* its *matter*, must still exist somewhere or other in undiminished quantity, whatever may have become of its *form*; likewise,

when we perceive a body suddenly in a place, where it was not before, that it must have been brought there or formed by some combination of invisible particles — for instance, by precipitation — but that it, *i.e.* its substance, cannot have then started into existence; for this implies a total impossibility and is utterly inconceivable. The certainty with which we assume this beforehand (*à priori*), proceeds from the fact, that our Understanding possesses absolutely no form under which to conceive the beginning and end of Matter. For, as before said, the law of causality — the only form in which we are able to conceive changes at all — is solely applicable to *states* of bodies, and never under any circumstances to the existence of *that which undergoes* all changes: *Matter*. This is why I place the principle of the permanence of Matter among the corollaries of the causal law. Moreover, we cannot have acquired *à posteriori* the conviction that substance is permanent, partly because it cannot, in most instances, be empirically established; partly also, because every empirical knowledge obtained exclusively by means of induction, has only approximate, consequently precarious, never unconditioned, certainty. The firmness of our persuasion as to this principle is therefore of a different kind and nature from our security of conviction with regard to the accuracy of any *empirically* discovered law of Nature, since it has an entirely different, perfectly unshakable, never vacillating firmness. The reason of this is, that the principle expresses a *transcendental* knowledge, *i.e.* one which determines and fixes, *prior* to all experience, what is in any way possible within the whole range of experience; but, precisely by this, it reduces the world of experience to a mere cerebral phenomenon. Even the most universal among the non-transcendental laws of Nature and the one least liable to exception — the law of gravitation — is of empirical origin, consequently without guarantee as to its absolute universality; wherefore it is still from time to time called in question, and doubts occasionally arise as to its validity beyond our solar system; and astronomers carefully call attention to any indications corroborative of its doubtfulness with which they may happen to meet, thereby showing that they regard it as merely empirical. The question may of course be raised, whether gravitation takes effect between bodies which are separated by an *absolute* vacuum, or whether its action within a solar system may not be mediated by some sort of ether, and may not cease altogether between fixed stars; but these questions only admit of an empirical solution, and this proves that here we have not to do with a

knowledge *à priori*. If, on the other hand, we admit with Kant and Laplace the hypothesis, as the most probable one, that each solar system has developed out of an original *nebula* by a gradual process of condensation, we still cannot for a moment conceive the possibility of that original substance having sprung into being out of *nothing*: we are forced to assume the anterior existence of its particles somewhere or other, as well as their having been brought together somehow or other, precisely because of the transcendental nature of the principle of the permanence of Substance. In my Critique of Kantian Philosophy,[65] I have shown at length, that *Substance* is but another word for *Matter*, the conception of substance not being realisable excepting in *Matter*, and therefore deriving its origin from *Matter*, and I have also specially pointed out how that conception was formed solely to serve a surreptitious purpose. Like many other equally certain truths, this eternity of Matter (called the permanence of substance) is forbidden fruit for professors of philosophy; so they slip past it with a bashful, sidelong glance.

By the endless chain of causes and effects which directs all *changes* but never extends beyond them, two existing things remain untouched, precisely because of the limited range of its action: on the one hand, *Matter*, as we have just shown; on the other hand, the primary *forces of Nature*. The first (matter) remains uninfluenced by the causal nexus, because it is *that which undergoes* all changes, or *on which* they take place; the second (the primary forces), because it is they alone *by which* changes or effects become possible; for they alone give causality to causes. *i.e.* the faculty of operating, which the causes therefore hold as mere vassals a fief. Cause and effect are *changes* connected together to necessary succession in Time; whereas the forces of Nature by means of which all causes operate, are exempt from all change; in this sense therefore they are outside Time, but precisely on that account they are always and everywhere in reserve, omnipresent and inexhaustible, ever ready to manifest themselves, as soon as an opportunity presents itself in the thread of causality. A *cause*, like its *effect*, is invariably something individual, a single change; whereas a force of Nature is something universal, unchangeable, present at all times and in all places. The attraction of a thread by amber, for instance, at the present moment, is an effect; its cause is the preceding friction and actual contact of the amber with the thread; and the *force of Nature* which acts in, and

presides over, the process, is Electricity. The explanation of this matter is to be found in my chief work,[66] and there I have shown in a long chain of causes and effects how the most heterogeneous natural forces successively come into play in them. By this explanation the difference between transitory phenomena and permanent forms of operation, becomes exceedingly clear; and as, moreover, a whole section (§ 26) is devoted to the question, it will be sufficient here to give a brief sketch of it. The *rule*, by which a force of Nature manifests itself in the chain of causes and effects — consequently the link which connects it with them — is the law of Nature. But the confusion between forces of Nature and causes is as frequent as it is detrimental to clearness of thought. It seems indeed as though no one had accurately defined the difference between these conceptions before me, however great may have been the urgency for such a distinction. Not only are forces of Nature turned into causes by such expressions as, 'Electricity, Gravity, &c., are the *cause* of so-and-so,' but they are even often turned into effects by those who search for a cause for Electricity, Gravity, &c. &c., which is absurd. Diminishing the number of the forces of Nature, however, by reducing one to another, as for instance Magnetism is in our days reduced to Electricity, is a totally different thing. Every *true*, consequently really primary force of Nature — and every fundamental chemical property belongs to these forces — is essentially a *qualitas occulta*, *i.e.* it does not admit of physical, but only of metaphysical explanation: in other words, of an explanation which transcends the world of phenomena. No one has carried this confusion, or rather identification, of causes with forces of Nature further than Maine de Biran in his "Nouvelles considérations des rapports du physique au moral," for it is essential to his philosophy. It is besides remarkable, that when he speaks of causes, he rarely uses the word *cause* alone, but almost always speaks of *cause ou force*, just as we have seen Spinoza above (§ 8) write *ratio sive causa* no less than eight times in the same page. Both writers are evidently conscious that they are identifying two disparates, in order to be able to make use of the one or the other, according to circumstances; for this end they are obliged to keep the identification constantly before their readers' mind. —

Now Causality, as the director of each and every change, presents itself in Nature under *three* distinct forms: as *causes* in the strictest acceptation of the word, as *stimuli*, and as *motives*. It is just upon this difference that the

real, essential distinction between inorganic bodies, plants, and animals is based, and not upon external, anatomical, let alone chemical, distinctions.

A *cause*, in its narrowest sense, is that upon which changes in the *inorganic* kingdom alone ensue: those changes, that is to say, which form the theme of Mechanics, Physics, and Chemistry. Newton's third fundamental law, "Action and reaction are equal to one another," applies exclusively to this cause, and enunciates, that the state which precedes (the cause) undergoes a change equivalent to that produced by it (the effect). In this form of causality alone, moreover, does the degree of the effect always exactly correspond to the degree of the cause, so as to enable us accurately to calculate the one by means of the other.

The second form of causality is the *stimulus*; it reigns over *organic* life, as such, *i.e.* over plant life and the vegetative, that is, the unconscious, part of animal life. This second form is characterized by the absence of the distinctive signs of the first. In it accordingly action and reaction are not equal, nor does the intensity of the effect by any means correspond throughout all its degrees to the intensity of the cause; in fact, the opposite effect may even be produced by intensifying the cause.

The third form of causality is the *motive*. Under this form causality rules animal life proper: that is, the exterior, consciously performed actions of all animals. The medium for motives is *knowledge*: an intellect is accordingly needed for susceptibility to motives. The true characteristic of the animal is therefore the faculty of knowing, of representing (*Das Vorstellen*). Animals, as such, always move towards some aim and end, which therefore must have been *recognised* by them: that is to say, it must have presented itself to them as something different from themselves, yet of which they are conscious. Therefore the proper definition of the animal would be: 'That which knows;' for no other definition quite hits the mark or can even perhaps stand the test of investigation. Movement induced by motives is necessarily wanting where there is no cognitive faculty, and movement by stimuli alone remains, *i.e.* plant life. Irritability and sensibility are therefore inseparable. Still motives evidently act in a different way from stimuli; for the action of the former may be very brief, nay, need only be momentary; since their efficacy, unlike that of stimuli, stands in no relation whatever to the duration of that action, to the proximity of the object, &c. &c. A motive needs but to be perceived therefore, to take effect; whereas stimuli always

require outward, often even inward, contact and invariably a certain length of time.

This short sketch of the three forms of causality will suffice here. They are more fully described in my Prize-essay on Free Will.[67] One thing, however, still remains to be urged. The difference between cause, stimulus, and motive, is obviously only a consequence of the various degrees of *receptivity* of beings; the greater their receptivity, the feebler may be the nature of the influence: a stone needs an impact, while man obeys a look. Nevertheless, both are moved by a sufficient cause, therefore with the same necessity. For '*motivation*'[68] is only causality passing through knowledge; the intellect is the medium of the motives, because it is the highest degree of receptivity. By this, however, the law of causality loses nothing whatever of its rigour and certainty; for motives are causes and operate with the same necessity which all causes bring with them. This necessity is easy to perceive in animals because of the greater simplicity of their intellect, which is limited to the perception of what is present. Man's intellect is double: for not only has he intuitive, but abstract, knowledge, which last is not limited to what is present. Man possesses Reason; he therefore has a power of elective decision with clear consciousness: that is, he is able to weigh against one another motives which exclude each other, as such; in other terms, he can let them try their strength on his will. The most powerful motive then decides him, and his actions ensue with just the same necessity as the rolling of a ball after it has been struck. Freedom of Will[69] means (not professorial twaddle but) "*that a given human being, in a given situation, can act in two different ways*." But the utter absurdity of this assertion is a truth as certain and as clearly proved, as any truth can be which passes the limits of pure mathematics. In my Essay on Free Will, to which the Norwegian Society awarded the prize, this truth is demonstrated more clearly, methodically, and thoroughly than has been done before by anyone else, and this moreover with special reference to those facts of our consciousness by which ignorant people imagine that absurdity to be confirmed. In all that is essential however, Hobbes, Spinoza, Priestley, Voltaire, and even Kant[70] already taught the same doctrine. Our professional philosophers, of course, do not let this interfere with their holding forth on Free Will, as if it were an understood thing which had never been questioned. But what do these gentlemen imagine the above-named great men to have come into the world for, by the grace of Nature? To enable

them (the professors) to earn their livelihood by philosophy? — Since I had proved this truth in my prize-essay more clearly than had ever been done before, and since moreover a Royal Society had sanctioned that proof by placing my essay among its memoranda, it surely behoved these worthies, considering the views they held, to make a vigorous attack upon so pernicious a doctrine, so detestable a heresy, and thoroughly to refute it. Nay, this duty was all the more imperative as, in my other essay "On the Foundation of Morality,"[71] I had proved the utter groundlessness of Kant's practical Reason with its Categorical Imperative which, under the name of the Moral Law, is still used by these gentlemen as the corner-stone of their own shallow systems of morality. I have shown it to be a futile assumption so clearly and irrefutably, that no one with a spark of judgment can possibly believe any longer in this fiction.— "Well, and so they probably did." — Oh no! They take good care not to venture on such slippery ground! Their ability consists in holding their tongues; silence is all they have to oppose to intelligence, earnestness, and truth. In not one of the products of their useless scribblings that have appeared since 1841, has the slightest notice been taken of my Ethics — undoubtedly the most important work on Moral Philosophy that has been published for the last sixty years — nay, their terror of me and of my truth is so great, that none of the literary journals issued by Academies or Universities has so much as mentioned the book. *Zitto, zitto*, lest the public should perceive anything: in this consists the whole of their policy. The instinct of self-preservation may, no doubt, be at the bottom of these artful tactics. For would not a philosophy, whose sole aim was truth, and which had no other consideration in view, be likely to play the part of the iron pot among the earthen ones, were it to come in contact with the petty systems composed under the influence of a thousand personal considerations by people whose chief qualification is the propriety of their sentiments? Their wretched fear of my writings is the fear of truth. Nor can it be denied, that precisely this very doctrine of the complete necessity of all acts of the will stands in flagrant contradiction with all the hypotheses of their favourite old-woman's philosophy cut after the pattern of Judaism. Still, that severely tested truth, far from being disturbed by all this, as a sure datum and criterion, as a true δός μοι ποῦ στῶ, proves the futility of all that old-woman's philosophy and the urgent need of a fundamentally different, incomparably deeper view of the Universe and of

Man; — no matter whether that view be compatible with the official duties of a professional philosopher or not.

§ 21. À priori *character of the conception of Causality.*
Intellectual Character of Empirical Perception.
THE UNDERSTANDING.

In the professorial philosophy of our philosophy-professors we are still taught to this day, that perception of the outer world is a thing of the senses, and then there follows a long dissertation upon each of the five senses: whereas no mention whatever is made of the intellectual character of perception: that is to say, of the fact, that it is mainly the work of the Understanding, which, by means of its own peculiar form of Causality, together with the forms of pure sensibility, Time and Space, which are postulated by Causality, primarily creates and produces the objective, outer world out of the raw material of a few sensations. And yet in its principal features, I had stated this matter in the first edition of the present treatise[72] and soon after developed it more fully in my treatise "On Vision and Colours" (1816), of which Professor Rosas has shown his appreciation by allowing it to lead him into plagiarism.[73] But our professors of philosophy have not thought fit to take the slightest notice either of this, or indeed of any of the other great and important truths which it has been the aim and labour of my whole life to set forth, in order to secure them as a lasting possession to mankind. It does not suit their tastes, or fit into their notions; it leads to no Theology, nor is it even adapted to drill students for higher State purposes. In short, professional philosophers do not care to learn from me, nor do they even see how much they might learn from me: that is, all that their children and their children's children will learn from me. They prefer to sit down and spin a long metaphysical yarn, each out of his own thoughts, for the benefit of the public; and no doubt, if fingers are a sufficient qualification, they have it. How right was Macchiavelli when he said, as Hesiod[74] before him: "There are three sorts of heads: firstly, those which acquire knowledge of things and comprehend them by themselves; secondly, those which recognise the truth when it is shown them by others; and thirdly, those which can do neither the one nor the other."[75] —

One must indeed be forsaken by all the gods, to imagine that the outer, perceptible world, filling Space in its three dimensions and moving on in

the inexorable flow of Time, governed at every step by the laws of Causality, which is without exception, and in all this merely obeying laws we can indicate before all experience of them — that such a world as this, we say, can have a real, objective existence outside us, without any agency of our own, and that it can then have found its way into our heads through bare sensation and thus have a second existence within us like the one outside. For what a miserably poor thing is mere sensation, after all! Even in the noblest of our organs it is nothing but a local, specific feeling, susceptible of some slight variation, still in itself always subjective and, as such therefore, incapable of containing anything objective, anything like perception. For sensation is and remains a process within the organism and is limited, as such, to the region within the skin; it cannot therefore contain anything which lies beyond that region, or, in other words, anything that is outside us. A sensation may be pleasant or unpleasant — which betokens a relation to the Will — but nothing objective can ever lie in any sensation. In the organs of the senses, sensation is heightened by the confluence of the nerve-extremities, and can easily be excited from without on account of their extensive distribution and the delicacy of the envelope which encloses them; it is besides specially susceptible to particular influences, such as light, sound, smell; notwithstanding which it is and remains mere sensation, like all others within our body, consequently something essentially subjective, of whose changes we only become immediately conscious in the form of the *inner* sense, Time: that is, successively. It is only when the *Understanding* begins to act — a function, not of single, delicate nerve-extremities, but of that mysterious, complicated structure weighing from five to ten pounds, called the brain — only when it begins to apply its sole form, *the causal law*, that a powerful transformation takes place, by which subjective sensation becomes objective perception. For, in virtue of its own peculiar form, therefore *à priori*, *i.e. before* all experience (since there could have been none till then), the Understanding conceives the given corporeal sensation as an *effect* (a word which the Understanding alone comprehends), which *effect*, as such, necessarily implies a *cause*. Simultaneously it summons to its assistance *Space*, the form of the *outer* sense, lying likewise ready in the intellect (*i.e.* the brain), in order to remove that cause *beyond* the organism; for it is by this that the external world first arises, Space alone rendering it possible, so that pure intuition *à priori* has to supply the foundation for empirical perception. In this process,

as I shall soon show more clearly, the Understanding avails itself of all the several data, even the minutest, which are presented to it by the given sensation, in order to construct the cause of it in Space in conformity with them. This intellectual operation (which is moreover explicitly denied both by Schelling[76] and by Fries[77]), does not however take place discursively or reflectively, *in abstracto*, by means of conceptions and words; it is, on the contrary, an intuitive and quite direct process. For by it alone, therefore exclusively *in* the Understanding and *for* the Understanding, does the real, objective, corporeal world, filling Space in its three dimensions, present itself and further proceed, according to the same law of causality, to change in Time, and to move in Space. — It is therefore the Understanding itself which has to create the objective world; for this world cannot walk into our brain from outside all ready cut and dried through the senses and the openings of their organs. In fact, the senses supply nothing but the raw materials which the Understanding at once proceeds to work up into the objective view of a corporeal world, subject to regular laws, by means of the simple forms we have indicated: Space, Time, and Causality. Accordingly our every-day *empirical perception* is an *intellectual* one and has a right to claim this predicate, which German pseudo-philosophers have given to a pretended intuition of dream-worlds, in which their beloved *Absolute* is supposed to perform its evolutions. And now I will proceed to show how wide is the gulf which separates sensation from perception, by pointing out how raw is the material out of which the beautiful edifice is constructed.

Objective perception makes use, properly speaking, of only two senses; touch and sight. These alone supply the data upon which, as its basis, the Understanding constructs the objective world by the process just described. The three other senses remain on the whole subjective; for their sensations, while pointing to an external cause, still contain no data by which its relations *in Space* can be determined. Now *Space* is the form of all perception, *i.e.* of *that* apprehension, in which alone *objects* can, properly speaking, present themselves. Therefore those other three senses can no doubt serve to announce the presence of objects we already know in some other way; but no construction in Space, consequently no objective perception, can possibly be founded on their data. A rose cannot be constructed from its perfume, and a blind man may hear music all his life without having the slightest objective representation either of the musicians,

or of the instruments, or of the vibrations of the air. On the other hand, the sense of hearing is of great value as a medium for language, and through this it is the sense of *Reason*. It is also valuable as a medium for music, which is the only way in which we comprehend numerical relations not only *in abstracto*, but directly, *in concreto*. A musical sound or tone, however, gives no clue to spacial relations, therefore it never helps to bring the nature of its cause nearer to us; we stop short at it, so that it is no datum for the Understanding in its construction of the objective world. The sensations of touch and sight alone are such data; therefore a blind man without either hands or feet, while able to construct Space for himself *à priori* in all its regularity, would nevertheless acquire but a very vague representation of the objective world. Yet what is supplied by touch and sight is not by any means perception, but merely the raw material for it. For perception is so far from being contained in the sensations of touch and sight, that these sensations have not even the faintest resemblance to the qualities of the things which present themselves to us through them, as I shall presently show. Only what really belongs to sensation must first be clearly distinguished from what is added to it by the intellect in perception. In the beginning this is not easy, because we are so accustomed to pass from the sensation at once to its cause, that the cause presents itself to us without our noticing the sensation apart from it, by which, as it were, the premisses are supplied to this conclusion drawn by the Understanding.

Thus touch and sight have each their own special advantages, to begin with; therefore they assist each other mutually. Sight needs no contact, nor even proximity; its field is unbounded and extends to the stars. It is moreover sensitive to the most delicate degrees of light, shade, colour, and transparency; so that it supplies the Understanding with a quantity of nicely defined data, out of which, by dint of practice, it becomes able to construct the shape, size, distance, and nature of bodies, and represents them at once perceptibly. On the other hand, touch certainly depends upon contact; still its data are so varied and so trustworthy, that it is the most searching of all the senses. Even perception by sight may, in the last resort, be referred to touch; nay, sight may be looked upon as an imperfect touch extending to a great distance, which uses the rays of light as long feelers; and it is just because it is limited to those qualities which have light for their medium and is therefore one-sided, that it is so liable to deception; whereas touch supplies the data for cognising size, shape, hardness, softness, roughness,

temperature, &c. &c., quite immediately. In this it is assisted, partly by the shape and mobility of our arms, hands, and fingers, from whose position in feeling objects the Understanding derives its data for constructing bodies in Space, partly by muscular power, which enables it to know the weight, solidity, toughness, or brittleness of bodies: all this with the least possible liability to error.

These data nevertheless do not by any means yet give perception, which is always the work of the Understanding. The sensation I have in pressing against a table with my hand, contains no representation of a firm cohesion of parts in that object, nor indeed anything at all like it. It is only when my Understanding passes from that sensation to its cause, that the intellect constructs for itself a body having the properties of solidity, impenetrability, and hardness. If in the dark, I put my hand upon a flat surface, or lay hold of a ball of about three inches in diameter, the same parts of my hand feel the pressure in both cases; it is only by the different position which my hand takes that, in the one or in the other case, my Understanding constructs the shape of the body whose contact is the cause of the sensation, for which it receives confirmation from the changes of position which I make. The sensations in the hand of a man born blind, on feeling an object of cubic shape, are quite uniform and the same on all sides and in every direction: the edges, it is true, press upon a smaller portion of his hand, still nothing at all like a cube is contained in these sensations. His Understanding, however, draws the immediate and intuitive conclusion from the resistance felt, that this resistance must have a cause, which then presents itself through that conclusion as a hard body; and through the movements of his arms in feeling the object, while the hand's sensation remains unaltered, he constructs the cubic shape in Space, which is known to him *à priori*. If the representation of a cause and of Space, together with their laws, had not already existed within him, the image of a cube could never have proceeded from those successive sensations in his hand. If a rope be drawn through his hand, he will construct, as the cause of the friction he feels and of its duration, a long cylindrical body, moving uniformly in the same direction in that particular position of his hand. But the representation of movement, *i.e.* of change of place in Space by means of Time, never could arise for him out of the mere sensation in his hand; for that sensation can neither contain, nor can it ever by itself alone produce any such thing. It is his intellect which must, on the contrary, contain within itself, before all experience, the

intuitions of Space, Time, and together with them that of the possibility of movement; and it must also contain the representation of Causality, in order to pass from sensation — which alone is given by experience — to a cause of that sensation, and to construct that cause as a body having this or that shape, moving in this or that direction. For how great is the difference between a mere sensation in my hand and the representations of causality, materiality, and mobility in Space by means of Time! The sensation in my hand, even if its position and its points of contact are altered, is a thing far too uniform and far too poor in data, to enable me to construct out of it the representation of Space, with its three dimensions, and of the influences of bodies one upon another, together with the properties of expansion, impenetrability, cohesion, shape, hardness, softness, rest, and motion: the basis, in short, of the objective world. This is, on the contrary, only possible by the intellect containing within itself, anterior to all experience, Space, as the form of perception; Time, as the form of change; and the law of Causality, as the regulator of the passing in and out of changes. Now it is precisely the pre-existence before all experience of all these forms, which constitutes the Intellect. Physiologically, it is a function of the brain, which the brain no more learns by experience than the stomach to digest, or the liver to secrete bile. Besides, no other explanation can be given of the fact, that many who were born blind, acquire a sufficiently complete knowledge of the relations of Space, to enable them to replace their want of eyesight by it to a considerable degree, and to perform astonishing feats. A hundred years ago Saunderson, for instance, who was blind from his birth, lectured on Optics, Mathematics, and Astronomy at Cambridge.[78] This, too, is the only way to explain the exactly opposite case of Eva Lauk, who was born without arms or legs, yet acquired an accurate perception of the outer world by means of sight alone as rapidly as other children.[79] All this therefore proves that Time, Space, and Causality are not conveyed into us by touch or by sight, or indeed at all from outside, but that they have an internal, consequently not empirical, but intellectual origin. From this again follows, that the perception of the bodily world is an essentially intellectual process, a work of the Understanding, to which sensation merely gives the opportunity and the data for application in individual cases.

I shall now prove the same with regard to the sense of sight. Here the only immediate datum is the sensation experienced by the retina, which, though admitting of great variety, may still be reduced to the impression of

light and dark with their intermediate gradations and to that of colours proper. This sensation is entirely subjective: that is to say, it only exists within the organism and under the skin. Without the Understanding, indeed, we should never even become conscious of these gradations, excepting as of peculiar, varied modifications of the feeling in our eye, which would bear no resemblance to the shape, situation, proximity, or distance of objects outside us. For *sensation*, in seeing, supplies nothing more than a varied affection of the retina, exactly like the spectacle of a painter's palette with divers splashes of colour. Nor would anything more remain over in our consciousness, were we suddenly deprived of all our Understanding — let us say by paralysis of the brain — at a moment when we were contemplating a rich and extensive landscape, while the sensation was left unchanged: for this was the raw material out of which our Understanding had just before been constructing that perception.

Now, that the Understanding should thus be able, from such limited material as light, shade and colour, to produce the visible world, inexhaustibly rich in all its different shapes, by means of the simple function of referring effects to causes assisted by the intuition of Space, depends before all things upon the assistance given by the sensation itself, which consists in this: first, that the retina, as a surface, admits of a juxtaposition of impressions; secondly, that light always acts in straight lines, and that its refraction in the eye itself is rectilinear; finally, that the retina possesses the faculty of immediately feeling from which direction the light comes that impinges upon it, and this can, perhaps, only be accounted for by the rays of light penetrating below the surface of the retina. But by this we gain, that the mere impression at once indicates the direction of its cause; that is, it points directly to the position of the object from which the light proceeds or is reflected. The passage to this object as a cause no doubt presupposes the knowledge of causal relations, as well as of the laws of Space; but this knowledge constitutes precisely the furniture of the *Intellect*, which, here also, has again to create perception out of mere sensation. Let us now examine its procedure in doing so more closely.

The first thing it does is to set right the impression of the object, which is produced on the retina upside down. That original inversion is, as we know, brought about in the following manner. As each point of the visible object sends forth its rays towards all sides in a rectilinear direction, the rays from its upper extremity cross those from its lower extremity in the narrow

aperture of the pupil, by which the former impinge upon the bottom, the latter upon the top, those projected from the right side upon the left, and *vice versa*. The refracting apparatus of the eye, which consists of the *humor aqueus*, *lens*, *et corpus vitreum*, only serves to concentrate the rays of light proceeding from the object, so as to find room for them on the small space of the retina. Now, if seeing consisted in mere sensation, we should perceive the impression of the object turned upside down, because we receive it thus; but in that case we should perceive it as something within our eye, for we should stop short at the sensation. In reality, however, the Understanding steps in at once with its causal law, and as it has received from sensation the datum of the direction in which the ray impinged upon the retina, it pursues that direction retrogressively up to the cause on both lines; so that this time the crossing takes place in the opposite direction, and the cause presents itself upright as an external object in Space, *i.e.* in the position in which it originally sent forth its rays, not that in which they reached the retina (see fig. 1). — The purely intellectual nature of this process, to the exclusion of all other, more especially of physiological, explanations, may also be confirmed by the fact, that if we put our heads between our legs, or lie down on a hill head downwards, we nevertheless see objects in their right position, and not upside down; although the portion of the retina, which is usually met by the lower part of the object is then met by the upper: in fact, everything is topsy turvy excepting the Understanding.

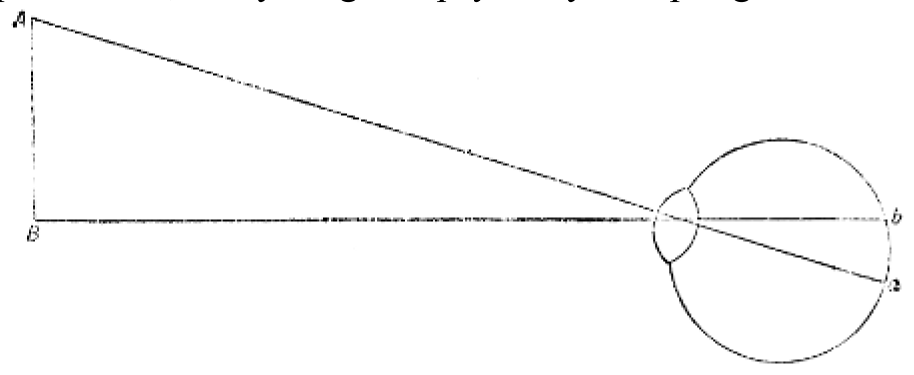

Fig. 1.

The *second* thing which the Understanding does in converting sensation into perception, is to make a single perception out of a double sensation; for each eye in fact receives its own separate impression from the object we are looking at; each even in a slightly different direction: nevertheless that object presents itself as a single one. This can only take place in the Understanding, and the process by which it is brought about is the

following: Our eyes are never quite parallel, excepting when we look at a distant object, *i.e.* one which is more than 200 feet from us. At other times they are both directed towards the object we are viewing, whereby they converge, so as to make the lines proceeding from each eye to the exact point of the object on which it is fixed, form an *angle*, called the *optic angle*; the lines themselves are called *optic axes*. Now, when the object lies straight before us, these lines exactly impinge upon the centre of each retina, therefore in two points which correspond exactly to each other in each eye. The Understanding, whose only business it is to look for the *cause* of all things, at once recognises the impression as coming from a *single* outside point, although here the sensation is double, and attributes it to *one* cause, which therefore presents itself as a single object. For all that is perceived by us, is perceived as a *cause* — that is to say, as the cause of an effect we have experienced, consequently *in the Understanding*. As, nevertheless, we take in not only a single point, but a considerable surface of the object with both eyes, and yet perceive it as a single object, it will be necessary to pursue this explanation still further. All those parts of the object which lie to one side of the vertex of the optic angle no longer send their rays straight into the centre, but to the side, of the retina in each eye; in both sides, however, to the same, let us say the left, side. The points therefore upon which these rays impinge, *correspond symmetrically to each other*, as well as the centres — in other words, they are *homonymous points*. The Understanding soon learns to know them, and accordingly extends the above-mentioned rule of its causal perception to them also; consequently it not only refers those rays which impinge upon the centre of each retina, but those also which impinge upon all the other symmetrically corresponding places in both retinas, to a single radiant point in the object viewed: that is, it sees all these points likewise as single, and the entire object also. Now, it should be well observed, that in this process it is not the outer side of one retina which corresponds to the outer side of the other, and the inner to the inner of each, but the right side of one retina which corresponds to the right side of the other, and so forth; so that this symmetrical correspondence must not be taken in a physiological, but in a geometrical sense. Numerous and very clear illustrations of this process, and of all the phenomena which are connected with it, are to be found in Robert Smith's "Optics," and partly also in Kästner's German translation (1755). I only give *one* (fig. 2), which, properly speaking, represents a special case, mentioned further on, but

which may also serve to illustrate the whole, if we leave the point R out of question. According to this illustration, we invariably direct both eyes equally towards the object, in order that the symmetrically corresponding places on both retinas may catch the rays projected from the same points. Now, when we move our eyes upwards and downwards, to the sides, and in all directions, the point in the object which first impinged upon the central point of each retina, strikes a different place every time, but in all cases one which, in each eye, corresponds to the place bearing the same name in the other eye. In examining (*perlustrare*) an object, we let our eyes glide backwards and forwards over it, in order to bring each point of it successively into contact with the centre of the retina, which sees most distinctly: we feel it all over with our eyes. It is therefore obvious that seeing singly with two eyes is in fact the same process as feeling a body with ten fingers, each of which receives a different impression, each moreover in a different direction: the totality of these impressions being nevertheless recognised by the Understanding as proceeding from *one* object, whose shape and size it accordingly apprehends and constructs in Space. This is why it is possible for a blind man to become a sculptor, as was the case, for instance, with the famous Joseph Kleinhaus, who died in Tyrol, 1853, having been a sculptor from his fifth year.[80] For, no matter from what cause it may have derived its data, perception is invariably an operation of the Understanding.

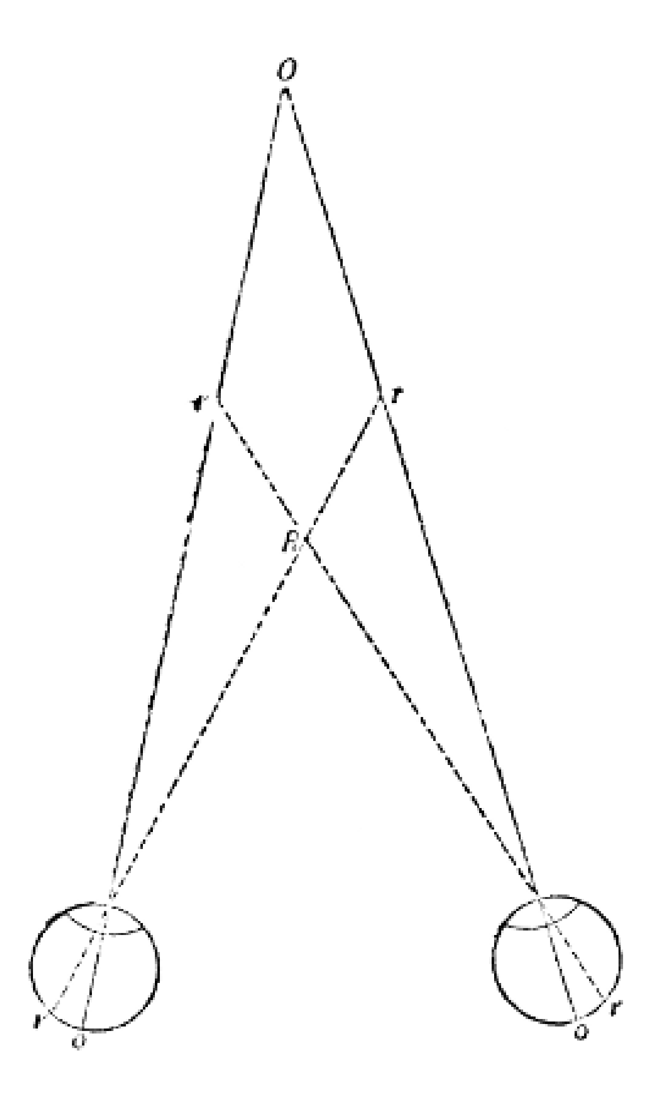

Fig. 2.

But just as a single ball seems to me double, if I touch it with my fingers crossed — since my Understanding, at once reverting to the cause and constructing it according to the laws of Space, takes for granted that the fingers are in their normal position and of course cannot do otherwise than attribute two spherical surfaces, which come in contact with the outer sides of the first and middle fingers, to two different balls — just so also does an object seem double, if my eyes, instead of converging symmetrically and enclosing the optic angle at a single point of the object, each view it at a different inclination — in other words, if I squint. For the rays, which in this case emanate from one point of the object, no longer impinge upon those symmetrically corresponding points in both retinas with which my mind has grown familiar by long experience, but upon other, quite different ones which, in a symmetrical position of the eyes, could only be affected in

this way by different bodies; I therefore now see *two* objects, precisely because perception takes place by means of, and within, the Understanding. — The same thing happens without squinting when, for instance, I look fixedly at the furthest of two objects placed at unequal distances before me, and complete the optic angle at it; for then the rays emanating from the nearer object do not impinge upon symmetrically corresponding places in both retinas, wherefore my Understanding attributes them to two objects, *i.e.* I see the nearer object double (see fig. 2, page 70). If, on the contrary, I complete the optic angle at the nearer object, by looking steadily at it, the further object appears double. It is easy to test this by holding a pencil two feet from the eyes, and looking alternately at it and at some other more distant object behind it.

But the finest thing of all is, that this experiment may quite well be reversed: so that, with two real objects straight before and close to us, and with our eyes wide open, we nevertheless see but *one*. This is the most striking proof that perception is a work of the Understanding and by no means contained in sensation. Let two cardboard tubes, about 8 inches long and 1-1/2 inches in diameter, be fastened parallel to one another, like those of a binocular telescope, and fix a shilling at the end of each tube. On applying our eyes to the opposite extremity and looking through the tubes, we shall see only *one* shilling surrounded by *one* tube. For in this case the eyes being forced into a completely parallel position, the rays emanating from the coins impinge exactly upon the centres of the two retinas and those points which immediately surround them, therefore upon places which correspond symmetrically to each other; consequently the Understanding, taking for granted the usual convergent position of the optic axes when objects are near, admits but one object as the cause of the reflected rays. In other words, we see but one object; so direct is the act of causal apprehension in the Understanding.

We have not space enough here to refute one by one the physiological explanations of single vision which have been attempted; but their fallacy is shown by the following considerations: —

1°. If seeing single were dependent upon an organic connection, the corresponding points in both retinas, on which this phenomenon is shown to depend, would correspond *organically*, whereas they do so in a merely *geometrical* sense, as has already been said. For, organically speaking, the two inner and two outer corners of the eyes are those which correspond, and

so it is with the other parts also; whereas for the purpose of single vision, it is the right side of the right retina which corresponds to the right side of the left retina, and so on, as the phenomena just described irrefutably show. It is also precisely on account of the intellectual character of the process, that only the most intelligent animals, such as the higher mammalia and birds of prey — more especially owls — have their eyes placed so as to enable them to direct both optic axes to the same point.

2°. The hypothesis of a confluence or partial intersection of the optic nerves before entering the brain, originated by Newton,[81] is false, simply because it would then be impossible to see double by squinting. Vesalius and Cæsalpinus besides have already brought forward anatomical instances in which subjects saw single, although neither fusion nor even contact of the optic nerves had taken place. A final argument against the hypothesis of a mixed impression is supplied by the fact, that on closing our right eye firmly and looking at the sun with our left, the bright image which persists for a time is always in the left, never in the right, eye: and *vice versa*.

The *third* process by which the Understanding converts sensation into perception, consists in constructing bodies out of the simple surfaces hitherto obtained — that is, in adding the third dimension. This it does by estimating the expansion of bodies in this third dimension in Space — which is known to the Understanding *à priori* — through Causality, according to the degree in which the eye is affected by the objects, and to the gradations of light and shade. In fact, although objects fill Space in all three dimensions, they can only produce an impression upon the eye with two; for the nature of that organ is such, that our sensation, in seeing, is merely planimetrical, not stereometrical. All that is stereometrical in our perception is added by the Understanding, which has for its sole data the direction whence the eye receives its impression, the limits of that impression, and the various gradations of light and dark: these data directly indicate their causes, and enable us to distinguish whether what we have before us is a disk or a ball. This mental process, like the preceding ones, takes place so immediately and with such rapidity, that we are conscious of nothing but the result. It is this which makes perspective drawing so difficult a problem, that it can only be solved by mathematics and has to be learnt; although all it has to do, is to represent the sensation of seeing as it presents itself to our Understanding as a datum for the third process: that is, visual sensation in its merely planimetrical extension, to the *two* dimensions

of which extension, together with the said data in them, the Understanding forthwith adds the *third*, in contemplating a drawing as well as in contemplating reality. Perspective drawing is, in fact, a sort of writing which can be read as easily as printed type, but which few are able to write; precisely because our intellect, in perceiving, only apprehends effects with a view to constructing their causes, immediately losing sight of the former as soon as it has discovered the latter. For instance, we instantly recognise a chair, whatever position it may be in; while drawing a chair in any position belongs to the art which abstracts from this third process of the Understanding, in order to present the data alone for the spectator himself to complete. In its narrowest acceptation, as we have already seen, this is the art of drawing in perspective; in a more comprehensive sense, it is the whole art of painting. A painting presents us with outlines drawn according to the rules of perspective; lighter and darker places proportioned to the effect of light and shade; finally patches of colouring, which are determined as to quality and intensity by the teaching of experience. This the spectator reads and interprets by referring similar effects to their accustomed causes. The painter's art consists in consciously retaining the data of visual sensation in the artist's memory, as they are *before* this third intellectual process; while we, who are not artists, cast them aside without retaining them in our memory, as soon as we have made use of them for the purpose described above. We shall become still better acquainted with this third intellectual process by now passing on to a fourth, which, from its intimate connection with the third, serves to elucidate it.

This *fourth* operation of the Understanding consists in acquiring knowledge of the distance of objects from us: it is this precisely which constitutes that third dimension of which we have been speaking. Visual sensation, as we have said, gives us the *direction* in which objects lie, but not their *distance* from us: that is, not their *position*. It is for the *Understanding* therefore to find out this distance; or, in other words, the distance must be inferred from purely *causal* determinations. Now the most important of these is the *visual angle*, which objects subtend; yet even this is quite ambiguous and unable to decide anything by itself. It is like a word of double meaning: the sense, in which it is to be understood, can only be gathered from its connection with the rest. An object subtending the same visual angle may in fact be small and near, or large and far off; and it is only when we have previously ascertained its size, that the visual angle enables

us to recognise its distance: and conversely, its size, when its distance is known to us. Linear perspective is based upon the fact that the visual angle diminishes as the distance increases, and its principles may here be easily deduced. As our sight ranges equally in all directions, we see everything in reality as from the interior of a hollow sphere, of which our eye occupies the centre. Now in the first place, an infinite number of intersecting circles pass through the centre of this sphere in all directions, and the angles measured by the divisions of these circles are the possible angles of vision. In the second place, the sphere itself modifies its size according to the length of radius we give to it; therefore we may also imagine it as consisting of an infinity of concentric, transparent spheres. As all radii diverge, these concentric spheres augment in size in proportion to their distance from us, and the degrees of their sectional circles increase correspondingly: therefore the true size of the objects which occupy them likewise increases. Thus objects are larger or smaller according to the size of the spheres of which they occupy similar portions — say 10° — while their visual angle remains unchanged in both cases, leaving it therefore undecided, whether the 10° occupied by a given object belong to a sphere of 2 miles, or of 10 feet diameter. Conversely, if the size of the object has been ascertained, the number of degrees occupied by it will diminish in proportion to the distance and the size of the sphere to which we refer it, and all its outlines will contract in similar proportion. From this ensues the fundamental law of all perspective; for, as objects and the intervals between them must necessarily diminish in constant proportion to their distance from us, all their outlines thereby contracting, the result will be, that with increasing distance, what is above us will descend, what is below us will ascend, and all that lies at our sides will come nearer together. This progressive convergence, this linear perspective, no doubt enables us to estimate distances, so far as we have before us an uninterrupted succession of visibly connected objects; but we are not able to do this by means of the visual angle alone, for here the help of another datum is required by the Understanding, to act, in a sense, as commentary to the visual angle, by indicating more precisely the share we are to attribute to distance in that angle. Now there are four principal data of this kind, which I am about to specify. Thanks to these data, even where there is no linear perspective to guide us, if a man standing at a distance of 200 feet appears to me subtending a visual angle twenty-four times smaller than if he were only 2 feet off, I can nevertheless in most cases estimate his

size correctly. All this proves once more that perception is not only a thing of the senses, but of the intellect also. — I will here add the following special and interesting fact in corroboration of what I have said about the basis of linear perspective as well as about the intellectual nature of all perception. When I have looked steadily at a coloured object with sharply defined outlines — say a red cross — long enough for the physiological image to form in my eye as a green cross, the further the surface on to which I project it, the larger it will appear to me: and *vice versa*. For the image itself occupies an unvarying portion of my retina, *i.e.* the portion originally affected by the red cross; therefore when referred outwards, or, in other words, recognised as the effect of an external object, it forms an unchanging visual angle, say of 2°. Now if, in this case, where all commentary to the visual angle is wanting, I remove it to a distant surface, with which I necessarily identify it as belonging to its effect, the cross will occupy 2° of a distant and therefore larger sphere, and is consequently large. If, on the other hand, I project the image on to a nearer object, it will occupy 2° of a smaller sphere, and is therefore small. The resulting perception is in both cases completely objective, quite like that of an external object; and as it proceeds from an entirely subjective reason (from the image having been excited in quite a different way), it thus confirms the intellectual character of all objective perception. — This phenomenon (which I distinctly remember to have been the first to notice, in 1815) forms the theme of an essay by Séguin, published in the "*Comptes rendus*" of the 2nd August, 1858, where it is served up as a new discovery, all sorts of absurd and distorted explanations of it being given. *Messieurs les illustres confrères* let pass no opportunity for heaping experiment upon experiment, the more complicated the better. *Expérience!* is their watchword; yet how rarely do we meet with any sound, genuine reflection upon the phenomena observed! *Expérience! expérience!* followed by twaddle.

To return to the subsidiary data which act as commentaries to a given visual angle, we find foremost among them the *mutationes oculi internæ*, by means of which the eye adapts its refractory apparatus to various distances by increasing and diminishing the refraction. In what these modifications consist, has not yet been clearly ascertained. They have been sought in the increased convexity, now of the *cornea*, now of the crystalline *lens*; but the latest theory seems to me the most probable one, according to which the lens is moved backwards for distant vision and forwards for near vision,

lateral pressure, in the latter case, giving it increased protuberance; so that the process would exactly resemble the mechanism of an opera-glass. Kepler, however, had, in the main, already expressed this theory, which may be found explained in A. Hueck's pamphlet, "Die Bewegung der Krystallinse," 1841. If we are not clearly conscious of these inner modifications of the eye, we have at any rate a certain feeling of them, and of this we immediately avail ourselves to estimate distances. As however these modifications are not available for the purposes of clear sight beyond the range of from about 7 inches to 16 feet, the Understanding is only able to apply this datum within those limits.

Beyond them, however, the second datum becomes available: that is to say, the *optic angle*, formed by the two optic axes, which we had occasion to explain when speaking of single vision. It is obvious that this optic angle becomes smaller, the further the object is removed: and *vice versa*. This different direction of the eyes, with respect to each other, does not take place without producing a slight sensation, of which we are nevertheless only in so far conscious as the Understanding makes use of it, as a datum, in estimating distances intuitively. By this datum we are not only enabled to cognize the distance, but the precise position of the object viewed, by means of the parallax of the eyes, which consists in each eye seeing the object in a slightly different direction; so that if we close one eye, the object seems to move. Thus it is not easy to snuff a candle with one eye shut, because this datum is then wanting. But as the direction of the eyes becomes parallel as soon as the distance of the object reaches or exceeds 200 feet, and as the optic angle consequently then ceases to exist, this datum only holds good within the said distance.

Beyond it, the Understanding has recourse to *atmospheric perspective*, which indicates a greater distance by means of the increasing dimness of all colours, of the appearance of physical blue in front of all dark objects (according to Göthe's perfectly correct and true theory of colours), and also of the growing indistinctness of all outlines. In Italy, where the atmosphere is very transparent, this datum loses its power and is apt to mislead: Tivoli, for instance, seems to be very near when seen from Frascati. On the other hand, all objects appear larger in a mist, which is an abnormal exaggeration of the datum; because our Understanding assumes them to be further from us.

Finally, there remains the estimation of distance by means of the size (known to us intuitively) of intervening objects, such as fields, woods, rivers, &c. &c. This mode of estimation is only applicable where there is uninterrupted succession: in other words, it can only be applied to terrestrial, not to celestial objects. Moreover, we have in general more practice in using it horizontally than vertically: a ball on the top of a tower 200 feet high appears much smaller to us than when lying on the ground 200 feet from us; because, in the latter case, we estimate the distance more accurately. When we see human beings in such a way, that what lies between them and ourselves is in a great measure hidden from our sight, they always appear strikingly small.

The fact that our Understanding assumes everything it perceives in a horizontal direction to be farther off, therefore larger, than what is seen in a vertical direction, must partly be attributed to this last mode of estimating distances, inasmuch as it only holds good when applied horizontally and to terrestrial objects; but partly also to our estimation of distances by atmospheric perspective, which is subject to similar conditions. This is why the moon seems so much larger on the horizon than at its zenith, although its visual angle accurately measured — that is, the image projected by it on to the eye — is not at all larger in one case than in the other; and this also accounts for the flattened appearance of the vault of the sky: that is to say, for its appearing to have greater horizontal than vertical extension. Both phenomena therefore are purely intellectual or cerebral, not optical. If it be objected, that even when at its zenith, the moon occasionally has a hazy appearance without seeming to be larger, we answer, that neither does it in that case appear red; for its haziness proceeds from a greater density of vapours, and is therefore of a different kind from that which proceeds from atmospheric perspective. To this may be added what I have already said: that we only apply this mode of estimating distances in a horizontal, not in a perpendicular, direction; besides, in this case, other correctives come into play. It is related of Saussure that, when on the Mont Blanc, he saw so enormous a moon rise, that, not recognising what it was, he fainted with terror.

The properties of the telescope and magnifying glass, on the other hand, depend upon a separate estimate according to the visual angle alone: *i.e.*, that of size by distance, and of distance by size; because here the four other supplementary means of estimating distances are excluded. The telescope in

reality magnifies objects, while it only seems to bring them nearer; because their size being known to us empirically, we here account for its apparent increase by a diminution of their distance from us. A house seen through a telescope, for instance, seems to be ten times nearer, not ten times larger, than seen with the naked eye. The magnifying glass, on the contrary, does not really magnify, but merely enables us to bring the object nearer to our eyes than would otherwise be possible; so that it only appears as large as it would at that distance even without the magnifying glass. In fact, we are prevented from seeing objects distinctly at less than from eight to ten inches' distance from our eyes, by the insufficient convexity of the ocular lens and cornea; but if we increase the refraction by substituting the convexity of the magnifying glass for that of the lens and cornea, we then obtain a clear image of objects even when they are as near as half an inch from our eyes. Objects thus seen in close proximity to us and in the size corresponding to that proximity, are transferred by our Understanding to the distance at which we naturally see distinctly, *i.e.* to about eight or ten inches from our eyes, and we then estimate their magnitude according to this distance and to the given visual angle.

I have entered thus fully into detail concerning all the different processes by which seeing is accomplished, in order to show clearly and irrefragably that the predominant factor in them is *the Understanding*, which, by conceiving each change as an *effect* and referring that effect to its *cause*, produces the cerebral phenomenon of the objective world on the basis of the *à priori* fundamental intuitions of Space and Time, for which it receives merely a few data from the senses. And moreover the Understanding effects this exclusively by means of its own peculiar form, the law of Causality; therefore quite directly and intuitively, without any assistance whatever from reflection — that is, from abstract knowledge by means of conceptions and of language, which are the materials of *secondary* knowledge, *i.e.* of *thought*, therefore of *Reason*.

That this knowledge through the Understanding is independent of Reason's assistance, is shown even by the fact, that when, at any time, the Understanding attributes a given effect to a wrong cause, actually perceiving that cause, whereby *illusion* arises, our Reason, however clearly it may recognise *in abstracto* the true state of the matter, is nevertheless unable to assist the Understanding, and the illusion persists undisturbed in spite of that better knowledge. The above-mentioned phenomena of seeing

and feeling double, which result from an abnormal position of the organs of touch and sight, are instances of such illusions; likewise the apparently increased size of the rising moon; the image which forms in the focus of a concave mirror and exactly resembles a solid body floating in space; the painted relievo which we take for real; the apparent motion of a shore or bridge on which we are standing, if a ship happens to pass along or beneath it; the seeming proximity of very lofty mountains, owing to the absence of atmospheric perspective, which is the result of the purity of the air round their summits. In these and in a multitude of similar cases, our Understanding takes for granted the existence of the usual cause with which it is conversant and forthwith perceives it, though our Reason has arrived at the truth by a different road; for, the knowledge of the Understanding being anterior to that of the Reason, the intellect remains inaccessible to the teaching of the Reason, and thus the *illusion* — that is, the deception of the Understanding — remains immovable; albeit *error* — that is, the deception of the Reason — is obviated. — That which is correctly known by the Understanding is *reality*: that which is correctly known by the Reason is *truth*, or in other terms, a judgment having a sufficient reason; *illusion* (that which is wrongly perceived) we oppose to *reality*: *error* (that which is wrongly thought) to *truth*.

The purely formal part of empirical perception — that is, Space, Time, and the law of Causality — is contained *à priori* in the intellect; but this is not the case with the application of this formal part to empirical data, which has to be acquired by the Understanding through practice and experience. Therefore new-born infants, though they no doubt receive impressions of light and of colour, still do not apprehend or indeed, strictly speaking, see objects. The first weeks of their existence are rather passed in a kind of stupor, from which they awaken by degrees when their Understanding begins to apply its function to the data supplied by the senses, especially those of touch and of sight, whereby they gradually gain consciousness of the objective world. This newly-arising consciousness may be clearly recognised by the look of growing intelligence in their eyes and a degree of intention in their movements, especially in the smile with which they show for the first time recognition of those who take care of them. They may even be observed to make experiments for a time with their sight and touch, in order to complete their apprehension of objects by different lights, in different directions and at different distances: thus pursuing a silent, but

serious course of study, till they have succeeded in mastering all the intellectual operations in seeing which have been described. The fact of this schooling can be ascertained still more clearly through those who, being born blind, have been operated upon late in life, since they are able to give an account of their impressions. Cheselden's blind man[82] was not an isolated instance, and we find in all similar cases the fact corroborated, that those who obtain their sight late in life, no doubt, see light, outlines, and colours, as soon as the operation is over, but that they have no objective perception of objects until their Understanding has learnt to apply its causal law to data and to changes which are new to it. On first beholding his room and the various objects in it, Cheselden's blind man did not distinguish one thing from another; he simply received the general impression of a totality all in one piece, which he took for a smooth, variegated surface. It never occurred to him to recognise a number of detached objects, lying one behind the other at different distances. With blind people of this sort, it is by the sense of touch, to which objects are already known, that they have to be introduced to the sense of sight. In the beginning, the patient has no appreciation whatever of distances and tries to lay hold of everything. One, when he first saw his own house from outside, could not conceive how so small a thing could contain so many rooms. Another was highly delighted to find, some weeks after the operation, that the engravings hanging on the walls of his room represented a variety of objects. The "Morgenblatt" of October 23rd, 1817, contains an account of a youth who was born blind, and obtained his sight at the age of seventeen. He had to learn intelligent perception, for at first sight he did not even recognise objects previously known to him through the sense of touch. Every object had to be introduced to the sense of sight by means of the sense of touch. As for the distances of the objects he saw, he had no appreciation whatever of them, and tried to lay hold indiscriminately of everything, far or near. — Franz expresses himself as follows:[83] —

"A definite idea of distance, as well as of form and size, is only obtained by sight and touch, and by reflecting on the impressions made on both senses; but for this purpose we must take into account the muscular motion and voluntary locomotion of the individual. — Caspar Hauser, in a detailed account of his own experience in this respect, states, that upon his first liberation from confinement, whenever he looked through the window upon external objects, such as the street, garden, &c., it appeared to him as if

there were a shutter quite close to his eye, and covered with confused colours of all kinds, in which he could recognise or distinguish nothing singly. He says farther, that he did not convince himself till after some time during his walks out of doors, that what had at first appeared to him as a shutter of various colours, as well as many other objects, were in reality very different things; and that at length the shutter disappeared, and he saw and recognised all things in their just proportions. Persons born blind who obtain their sight by an operation in later years only, sometimes imagine that all objects touch their eyes, and lie so near to them that they are afraid of stumbling against them; sometimes they leap towards the moon, supposing that they can lay hold of it; at other times they run after the clouds moving along the sky, in order to catch them, or commit other such extravagancies. Since ideas are gained by reflection upon sensation, it is further necessary in all cases, in order that an accurate idea of objects may be formed from the sense of sight, that the powers of the mind should be unimpaired, and undisturbed in their exercise. A proof of this is afforded in the instance related by Haslam,[84] of a boy who had no defect of sight, but was weak in understanding, and who in his seventh year was unable to estimate the distances of objects, especially as to height; he would extend his hand frequently towards a nail on the ceiling, or towards the moon, to catch it. It is therefore the judgment which corrects and makes clear this idea, or perception of visible objects."

The intellectual nature of perception as I have shown it, is corroborated physiologically by Flourens[85] as follows:

"Il faut faire une grand distinction entre les sens et l'intelligence. L'ablation d'un tubercule détermine la perte de la *sensation*, du *sens* de la vue; la rétine devient insensible, l'iris devient immobile. L'ablation d'un lobe cérébral laisse la *sensation*, le *sens*, la *sensibilité* de la rétine, la *mobilité* de l'iris; elle ne détruit que la *perception* seule. Dans un cas, c'est un fait *sensorial*; et, dans l'autre, un fait *cérébral*; dans un cas, c'est la perte du *sens*; dans l'autre, c'est la perte de la *perception*. La distinction des perceptions et des sensations est encore un grand résultat; et it est démontré aux yeux. Il y a deux moyens de faire perdre la vision par l'encéphale: 1° par les tubercules, c'est la perte du sens, de la sensation; 2° par les lobes, c'est la perte de la perception, de l'intelligence. La sensibilité n'est donc pas l'intelligence; penser n'est donc pas sentir; et voilà toute une philosophie renversée. L'idée n'est donc pas la sensation; et voilà encore une autre

preuve du vice radical de cette philosophie.” And again, p. 77, under the heading: Séparation de la Sensibilité et de la Perception:— “Il y a une de mes expériences qui sépare nettement la *sensibilité* de la *perception*. Quand on enlève le *cerveau proprement dit* (*lobes* ou *hémisphères cérébraux*) à un animal, l’animal perd la vue. Mais, par rapport a l’œil, rien n’est changé: les objets continuent à se peindre sur la rétine; l’*iris* reste contractile, le *nerf optique* sensible, parfaitement sensible. Et cependant l’animal ne voit plus; il n’y a plus *vision*, quoique tout ce qui est *sensation* subsiste; il n’y a plus *vision*, parce qu’il n’y a plus *perception*. Le *percevoir*, et non le *sentir*, est donc le premier élément de l’*intelligence*. La *perception* est partie de l’*intelligence*, car elle se perd avec l’*intelligence*, et par l’ablation du même organe, les *lobes* ou *hémisphères cérébraux*; et la *sensibilité* n’en est point partie, puisqu’elle subsiste après la perte de l’*intelligence* et l’ablation des *lobes* ou *hémisphères*.”

The following famous verse of the ancient philosopher Epicharmus, proves that the ancients in general recognized the intellectual nature of perception: Νοῦς ὁρῇ καὶ νοῦς ἀκούει· τἄλλα κωφὰ καὶ τυφλά. (*Mens videt, mens audit; cætera surda et cæca.*)[86] Plutarch in quoting this verse, adds:[87] ὡς τοῦ περὶ τὰ ὄμματα καὶ ὦτα πάθους, ἂν μὴ παρῇ τὸ φρονοῦν, αἴσθησιν οὐ ποιοῦντος (*quia affectio oculorum et aurium nullum affert sensum, intelligentia absente*). Shortly before too he says: Στράτωνος τοῦ φυσικοῦ λόγος ἐστίν, ἀποδεικνύων ὡς οὐδ’ αἰσθάνεσθαι τοπαράπαν ἄνευ τοῦ νοεῖν ὑπάρχει. (*Stratonis physici exstat ratiocinatio, qua “sine intelligentia sentiri omnino nihil posse” demonstrat.*)[88] Again shortly after he says: ὅθεν ἀνάγκη, πᾶσιν, οἷς τὸ αἰσθάνεσθαι, καὶ τὸ νοεῖν ὑπάρχειν, εἰ τῷ νοεῖν αἰσθάνεσθαι πεφύκαμεν (*quare necesse est, omnia, quæ sentiunt, etiam intelligere, siquidem intelligendo demum sentiamus*).[89] A second verse of Epicharmus might be connected with this, which is quoted by Diogenes Laertes (iii. 16):

Εὔμαιε, τὸ σοφόν ἐστιν οὐ καθ’ ἓν μόνον,
ἀλλ’ ὅσα περ ζῇ, πάντα καὶ γνώμαν ἔχει.

(*Eumaee, sapientia non uni tantum competit, sed quæcunque vivunt etiam intellectum habent.*) Porphyry likewise endeavours to show at length that all animals have understanding.[90]

Now, that it should be so, follows necessarily from the intellectual character of perception. All animals, even down to the very lowest, must

have Understanding — that is, knowledge of the causal law, although they have it in very different degrees of delicacy and of clearness; at any rate they must have as much of it as is required for perception by their senses; for sensation without Understanding would be not only a useless, but a cruel gift of Nature. No one, who has himself any intelligence, can doubt the existence of it in the higher animals. But at times it even becomes undeniably evident that their knowledge of causality is actually *à priori*, and that it does not arise from the habit of seeing one thing follow upon another. A very young puppy will not, for instance, jump off a table, because he foresees what would be the consequence. Not long ago I had some large curtains put up at my bed-room window, which reached down to the floor, and were drawn aside from the centre by means of a string. The first morning they were opened I was surprised to see my dog, a very intelligent poodle, standing quite perplexed, and looking upwards and sidewards for the cause of the phenomenon: that is, he was seeking for the change which he knew *à priori* must have taken place. Next day the same thing happened again. — But even the lowest animals have perception — consequently Understanding — down to the aquatic polypus, which has no distinct organs of sensation, yet wanders from leaf to leaf on its waterplant, while clinging to it with its feelers, in search of more light.

Nor is there, indeed, any difference, beyond that of degree, between this lowest Understanding and that of man, which we however distinctly separate from his Reason. The intermediate gradations are occupied by the various series of animals, among which the highest, such as the monkey, the elephant, the dog, astonish us often by their intelligence. But in every case the business of the Understanding is invariably to apprehend directly causal relations: first, as we have seen, those between our own body and other bodies, whence proceeds objective perception; then those between these objectively perceived bodies among themselves, and here, as has been shown in § 20, the causal relation manifests itself in three forms — as cause, as stimulus, and as motive. All movement in the world takes place according to these three forms of the causal relation, and through them alone does the intellect comprehend it. Now, if, of these three, *causes*, in the narrowest sense of the word, happen to be the object of investigation for the Understanding, it will produce Astronomy, Mechanics, Physics, Chemistry, and will invent machines for good and for evil; but in all cases a direct, intuitive apprehension of the causal connection will in the last resort lie at

the bottom of all its discoveries. For the sole form and function of the Understanding is this apprehension, and not by any means the complicated machinery of Kant's twelve Categories, the nullity of which I have proved. — (All comprehension is a direct, consequently intuitive, apprehension of the causal connection; although this has to be reduced at once to abstract conceptions in order to be fixed. To calculate therefore, is not to understand, and, in itself, calculation conveys no comprehension of things. Calculation deals exclusively with abstract conceptions of magnitudes, whose mutual relations it determines. By it we never attain the slightest comprehension of a physical process, for this requires *intuitive* comprehension of space-relations, by means of which causes take effect. Calculations have merely practical, not theoretical, value. It may even be said that *where calculation begins, comprehension ceases*; for a brain occupied with numbers is, as long as it calculates, entirely estranged from the causal connection in physical processes, being engrossed in purely abstract, numerical conceptions. The result, however, only shows us *how much*, never *what*. "*L'expérience et le calcul*," those watchwords of French physicists, are not therefore by any means adequate [for thorough insight].) — If, again, *stimuli* are the guides of the Understanding, it will produce Physiology of Plants and Animals, Therapeutics, and Toxicology. Finally, if it devotes itself to the study of *motives*, the Understanding will use them, on the one hand, theoretically, to guide it in producing works on Morality, Jurisprudence, History, Politics, and even Dramatic and Epic Poetry; on the other hand, practically, either merely to train animals, or for the higher purpose of making human beings dance to its music, when once it has succeeded in discovering which particular wire has to be pulled in order to move each puppet at its pleasure. Now, with reference to the function which effects this, it is quite immaterial whether the intellect turns gravitation ingeniously to account, and makes it serve its purpose by stepping in just at the right time, or whether it brings the collective or the individual propensities of men into play for its own ends. In its practical application we call the Understanding *shrewdness* or, when used to outwit others, *cunning*; when its aims are very insignificant, it is called *slyness* and, if combined with injury to others, *craftiness*. In its purely theoretical application, we call it simply *Understanding*, the higher degrees of which are named *acumen*, *sagacity*, *discernment*, *penetration*, while its lower degrees are termed *dulness*, *stupidity*, *silliness*, &c. &c. These widely

differing degrees of sharpness are innate, and cannot be acquired; although, as I have already shown, even in the earliest stages of the application of the Understanding, *i.e.* in empirical perception, practice and knowledge of the material to which it is applied, are needed. Every simpleton has Reason — give him the premisses, and he will draw the conclusion; whereas *primary*, consequently intuitive, knowledge is supplied by the Understanding: herein lies the difference. The pith of every great discovery, of every plan having universal historical importance, is accordingly the product of a happy moment in which, by a favourable coincidence of outer and inner circumstances, some complicated causal series, some hidden causes of phenomena which had been seen thousands of times before, or some obscure, untrodden paths, suddenly reveal themselves to the intellect. —

By the preceding explanations of the processes in seeing and feeling, I have incontestably shown that empirical perception is essentially the work of *the Understanding*, for which the material only is supplied by the senses in sensation — and a poor material it is, on the whole; so that *the Understanding* is, in fact, the artist, while the senses are but the under-workmen who hand it the materials. But the process consists throughout in referring from given effects to their causes, which by this process are enabled to present themselves as objects in Space. The very fact that we presuppose Causality in this process, proves precisely that this law must have been supplied by the Understanding itself; for it could never have found its way into the intellect from outside. It is indeed the first condition of all empirical perception; but this again is the form in which all external experience presents itself to us; how then can this law of Causality be derived from experience, when it is itself essentially presupposed by experience? — It was just because of the utter impossibility of this, and because Locke's philosophy had put an end to all *à priority*, that Hume denied the whole reality of the conception of Causality. He had besides already mentioned two false hypotheses in the seventh section of his "Inquiry concerning the Human Understanding," which recently have again been advanced: the one, that the effect of the will upon the members of our body; the other, that the resistance opposed to our pressure by outward objects, is the origin and prototype of the conception of Causality. Hume refutes both in his own way and according to his own order of ideas. I argue as follows. There is no causal connection whatever between acts of the will and actions of the body; on the contrary, both are immediately one and the

same thing, only perceived in a double aspect — that is, on the one hand, in our self-consciousness, or inner sense, as acts of the will; on the other, simultaneously in exterior, spacial brain-perception, as actions of the body.[91] The second hypothesis is false, first because, as I have already shown at length, a mere sensation of touch does not yet give any objective perception whatever, let alone the conception of Causality, which never can arise from the feeling of an impeded muscular effort: besides impediments of this kind often occur without any external cause; secondly, because our pressing against an external object necessarily has a motive, and this already presupposes apprehension of that object, which again presupposes knowledge of Causality. — But the only means of radically proving the conception of Causality to be independent of all experience was by showing, as I have done, that the whole possibility of experience is conditioned by the conception of Causality. In § 23 I intend to show that Kant's proof, propounded with a similar intent, is false.

This is also the proper place for drawing attention to the fact, that Kant either did not clearly recognise in empirical perception the mediation of the causal law — which law is known to us before all experience — or that he intentionally evaded mentioning it, because it did not suit his purpose. In the "Critique of Pure Reason," for instance, the relation between causality and perception is not treated in the "Doctrine of Elements," but in the chapter on the "Paralogisms of Pure Reason," where one would hardly expect to find it; moreover it appears in his "Critique of the Fourth Paralogism of Transcendental Psychology," and only in the first edition.[92] The very fact that this place should have been assigned to it, shows that in considering this relation, he always had the transition from the phenomenon to the thing in itself exclusively in view, but not the genesis of perception itself. Here accordingly he says that the existence of a real external object is not given directly in perception, but can be added to it in thought and thus inferred. In Kant's eyes, however, he who does this is a Transcendental Realist, and consequently on a wrong road. For by his "outward object" Kant here means the thing in itself. The Transcendental Idealist, on the contrary, stops short at the perception of something empirically real — that is, of something existing outside us in Space — without needing the inference of a cause to give it reality. For *perception*, according to Kant, is quite directly accomplished without any assistance from the causal nexus, and consequently from the Understanding: he simply identifies perception

with sensation. This we find confirmed in the passage which begins, “With reference to the reality of external objects, I need as little trust to inference,” &c. &c.[93] and again in the sentence commencing with “Now we may well admit,” &c. &c.[94] It is quite clear from these passages that perception of external things in Space, according to Kant, precedes all application of the causal law, therefore that the causal law does not belong to perception as an element and condition of it: for him, mere sensation is identical with perception. Only in as far as we ask what may, in a *transcendental* sense, exist *outside of us*: that is, when we ask for the thing in itself, is Causality mentioned as connected with perception. Moreover Kant admits the existence, nay, the mere possibility, of causality only in reflection: that is, in abstract, distinct knowledge by means of conceptions; therefore he has no suspicion that its application is *anterior to all reflection*, which is nevertheless evidently the case, especially in empirical, sensuous perception which, as I have proved irrefragably in the preceding analysis, could never take place otherwise. Kant is therefore obliged to leave the genesis of empirical perception unexplained. With him it is a mere matter of the senses, given as it were in a miraculous way: that is, it coincides with sensation. I should very much like my reflective readers to refer to the passages I have indicated in Kant’s work, in order to convince themselves of the far greater accuracy of my view of the whole process and connection. Kant’s extremely erroneous view has held its ground till now in philosophical literature, simply because no one ventured to attack it; therefore I have found it necessary to clear the way in order to throw light upon the mechanism of our knowledge.

Kant’s fundamental idealistic position loses nothing whatever, nay, it even gains by this rectification of mine, in as far as, with me, the necessity of the causal law is absorbed and extinguished in empirical perception as its product and cannot therefore be invoked in behalf of an entirely transcendent question as to the thing in itself. On referring to my theory above concerning empirical perception, we find that its first datum, sensation, is absolutely subjective, being a process within the organism, because it takes place beneath the skin. Locke has completely and exhaustively proved, that the feelings of our senses, even admitting them to be roused by external causes, cannot have any resemblance whatever to the qualities of those causes. Sugar, for instance, bears no resemblance at all to sweetness, nor a rose to redness. But that they should need an external

cause at all, is based upon a law whose origin lies demonstrably within us, in our brain; therefore this necessity is not less subjective than the sensations themselves. Nay, even *Time* — that primary condition of every possible *change*, therefore also of the change which first permits the application of the causal law — and not less *Space* — which alone renders the externalisation of causes possible, after which they present themselves to us as objects — even Time and Space, we say, are subjective forms of the intellect, as Kant has conclusively proved. Accordingly we find all the elements of empirical perception lying within us, and nothing contained in them which can give us reliable indications as to anything differing absolutely from ourselves, anything in itself. — But this is not all. What we think under the conception *matter*, is the residue which remains over after bodies have been divested of their shape and of all their specific qualities: a residue, which precisely on that account must be identical in all bodies. Now these shapes and qualities which have been abstracted by us, are nothing but the peculiar, specially defined *way in which these bodies act*, which constitutes precisely their difference. If therefore we leave these shapes and qualities out of consideration, there remains nothing but *mere activity in general*, pure action as such, Causality itself, objectively thought — that is, the reflection of our own Understanding, the externalised image of its sole function; and Matter is throughout pure Causality, its essence is Action in general.[95] This is why pure Matter cannot be perceived, but can only be thought: it is a something we add to every reality, as its basis, in thinking it. For pure Causality, mere action, without any defined mode of action, cannot become perceptible, therefore it cannot come within any experience. — Thus Matter is only the objective correlate to pure Understanding; for it is Causality in general, and nothing else: just as the Understanding itself is direct knowledge of cause and effect, and nothing else. Now this again is precisely why the law of causality is not applicable to Matter itself: that is to say, Matter has neither beginning nor end, but is and remains permanent. For as, on the one hand, Causality is the indispensable condition of all alternation in the accidents (forms and qualities) of Matter, *i.e.* of all passage in and out of being; but as, on the other hand, Matter is pure Causality itself, as such, objectively viewed: it is unable to exercise its own power upon itself, just as the eye can see everything but itself. "Substance" and Matter being moreover identical, we may call *Substance*, *action* viewed *in abstracto*: *Accidents*, particular modes

of action, action *in concreto*. — Now these are the results to which true, *i.e.* transcendental, Idealism leads. In my chief work I have shown that the thing in itself — *i.e.* whatever, on the whole, exists independently of our representation — cannot be got at by way of representation, but that, to reach it, we must follow quite a different path, leading through the inside of things, which lets us into the citadel, as it were, by treachery. —

But it would be downright chicanery, nothing else, to try and compare, let alone identify, such an honest, deep, thorough analysis of empirical perception as the one I have just given, which proves all the elements of perception to be subjective, with Fichte's algebraic equations of the *Ego* and the *Non-Ego*; with his sophistical pseudo-demonstrations, which in order to be able to deceive his readers had to be clothed in the obscure, not to say absurd, language adopted by him; with his explanations of the way in which the *Ego* spins the *Non-Ego* out of itself; in short, with all the buffoonery of scientific emptiness.[96] Besides, I protest altogether against any community with this Fichte, as Kant publicly and emphatically did in a notice *ad hoc* in the "Jenaer Litteratur Zeitung."[97] Hegelians and similar ignoramuses may continue to hold forth to their heart's content upon Kant-Fichteian philosophy: there exists a Kantian philosophy and a Fichteian hocus-pocus, — this is the true state of the case, and will remain so, in spite of those who delight in extolling what is bad and in decrying what is good, and of these Germany possesses a larger number than any other country.

§ 22. *Of the Immediate Object.*

Thus it is from the sensations of our body that we receive the data for the very first application of the causal law, and it is precisely by that application that the perception of this class of objects arises. They therefore have their essence and existence solely in virtue of the intellectual function thus coming into play, and of its exercise.

Now, as far as it is the starting-point, *i.e.* the mediator, for our perception of all other objects, I have called the bodily organism, in the first edition of the present work, the *Immediate Object*; this, however, must not be taken in a strictly literal sense. For although our bodily sensations are all apprehended directly, still this immediate apprehension does not yet make our body itself perceptible to us as an object; on the contrary, up to this point all remains subjective, that is to say, sensation. From this sensation

certainly proceeds the perception of all other objects as the causes of such sensations, and these causes then present themselves to us as objects; but it is not so with the body itself, which only supplies sensations to consciousness. It is only *indirectly* that we know even this body objectively, *i.e.* as an object, by its presenting itself, like all other objects, as the recognised cause of a subjectively given effect — and precisely on this account *objectively* — in our Understanding, or brain (which is the same). Now this can only take place when its own senses are acted upon by its parts: for instance, when the body is seen by the eye, or felt by the hand, &c., upon which data the brain (or understanding) forthwith constructs it as to shape and quality in space. — The immediate presence in our consciousness of representations belonging to this class, depends therefore upon the position assigned to them in the causal chain — by which all things are *connected* — relatively to the body (for the time being) of the Subject — by which (the Subject) all things are *known*.

§ 23. *Arguments against Kant's Proof of the* à priority *of the conception of Causality*.

One of the chief objects of the "Critique of Pure Reason" is to show the universal validity, for all experience, of the causal law, its *à priority*, and, as a necessary consequence of this, its restriction to possible experience. Nevertheless, I cannot assent to the proof there given of the *à priority* of the principle, which is substantially this:— "The *synthesis* of the manifold by the imagination, which is necessary for all empirical knowledge, gives succession, but not yet determinate succession: that is, it leaves undetermined which of two states perceived was the first, not only in my imagination, but in the object itself. But definite order in this succession — through which alone what we perceive becomes experience, or, in other words, authorizes us to form objectively valid judgments — is first brought into it by the purely intellectual conception of cause and effect. Thus the principle of causal relation is the condition which renders experience possible, and, as such, it is given us *à priori*."[98]

According to this, the order in which changes succeed each other in real objects becomes known to us as objective only by their causality. This assertion Kant repeats and explains in the "Critique of Pure Reason," especially in his "Second Analogy of Experience,"[99] and again at the

conclusion of his "Third Analogy," and I request every one who desires to understand what I am now about to say, to read these passages. In them he affirms everywhere that *the objectivity of the succession of representations* — which he defines as their correspondence with the succession of real objects — is only known through the rule by which they follow upon one another: that is, through the law of causality; that my mere apprehension consequently leaves the objective relation between phenomena following one another quite undetermined: since I merely apprehend the succession of my own representations, but the succession in my apprehension does not authorize me to form any judgment whatever as to the succession in the object, unless that judgment be based upon causality; and since, besides, I might invert the order in which these perceptions follow each other in my apprehension, there being nothing which determines them as objective. To illustrate this assertion, Kant brings forward the instance of a house, whose parts we may consider in any order we like, from top to bottom, or from bottom to top; the determination of succession being in this case purely subjective and not founded upon an object, because it depends upon our pleasure. In opposition to this instance, he brings forward the perception of a ship sailing down a river, which we see successively lower and lower down the stream, which perception of the successively varying positions of the ship cannot be changed by the looker-on. In this latter case, therefore, he derives the subjective following in his own apprehension from the objective following in the phenomenon, and on this account he calls it an *event*. Now I maintain, on the contrary, that *there is no difference at all between these two cases, that both are events*, and that our knowledge of both is objective: that is to say, it is knowledge of changes in real objects recognized as such by the Subject. *Both are changes of relative position in two bodies.* In the first case, one of these bodies is a part of the observer's own organism, the eye, and the other is the house, with respect to the different parts of which the eye successively alters its position. In the second, it is the ship which alters its position towards the stream; therefore the change occurs between two bodies. Both are events, the only difference being that, in the first, the change has its starting-point in the observer's own body, from whose sensations undoubtedly all his perceptions originally proceed, but which is nevertheless an object among objects, and in consequence obeys the laws of the objective, material world. For the observer, as a purely cognising individual, any movement of his body is simply an empirically perceived

fact. It would be just as possible in the second as in the first instance, to invert the order of succession in the change, were it as easy for the observer to move the ship up the stream as to alter the direction of his own eyes. For Kant infers the successive perception of different parts of the house to be neither objective nor an event, because it depends upon his own will. But the movement of his eyes in the direction from roof to basement is one event, and in the direction from basement to roof another event, just as much as the sailing of the ship. There is no difference whatever here, nor is there any difference either, as to their being or not being events, between my passing a troop of soldiers and their passing me. If we fix our eyes on a ship sailing close by the shore on which we are standing, it soon seems as if it were the ship that stood still and the shore that moved. Now, in this instance we are mistaken, it is true, as to the cause of the relative change of position, since we attribute it to a wrong cause; the real succession in the relative positions of our body towards the ship is nevertheless quite rightly and objectively recognised by us. Even Kant himself would not have believed that there was any difference, had he borne in mind that his own body was an object among objects, and that the succession in his empirical perceptions depended upon the succession of the impressions received from other objects by his body, and was therefore an objective succession: that is to say, one which takes place among objects *directly* (if not indirectly) and independently of the will of the Subject, and which may therefore be quite well recognised without any causal connection between the objects acting successively on his body.

Kant says, Time cannot be perceived; therefore no succession of representations can be empirically perceived as objective: *i.e.* can be distinguished as changes in phenomena from the changes of mere subjective representations. The causal law, being a rule according to which states follow one another, is the only means by which the objectivity of a change can be known. Now, the result of his assertion would be, that no succession in Time could be perceived by us as objective, excepting that of cause and effect, and that every other succession of phenomena we perceive, would only be determined so, and not otherwise, by our own will. In contradiction to all this I must adduce the fact, that it is quite possible for phenomena to *follow upon* one another without *following from* one another. Nor is the law of causality by any means prejudiced by this; for it remains certain that each change is the effect of another change, this being firmly established *à*

priori; only each change not only follows upon the single one which is its cause, but upon all the other changes which occur simultaneously with that cause, and with which that cause stands in no causal connection whatever. It is not perceived by me exactly in the regular order of causal succession, but in quite a different order, which is, however, no less objective on that account, and which differs widely from any subjective succession depending on my caprice, such as, for instance, the pictures of my imagination. The succession, in Time, of events which stand in no causal connection with each other is precisely what we call *contingency*.[100] Just as I am leaving my house, a tile happens to fall from the roof which strikes me; now, there is no causal connection whatever between my going out and the falling of the tile; yet the order of their succession — that is, that my going out preceded the falling of the tile — is objectively determined in my apprehension, not subjectively by my will, by which that order would otherwise have most likely been inverted. The order in which tones follow each other in a musical composition is likewise objectively determined, not subjectively by me, the listener; yet who would think of asserting that musical tones follow one another according to the law of cause and effect? Even the succession of day and night is undoubtedly known to us as an objective one, but we as certainly do not look upon them as causes and effects of one another; and as to their common cause, the whole world was in error till Copernicus came; yet the correct knowledge of their succession was not in the least disturbed by that error. Hume's hypothesis, by the way, also finds its refutation through this; since the following of day and night upon each other — the most ancient of all successions and the one least liable to exception — has never yet misled anyone into taking them for cause and effect of each other.

Elsewhere Kant asserts, that a representation only shows reality (which, I conclude, means that it is distinguished from a mere mental image) by our recognising its necessary connection with other representations subject to rule (the causal law) and its place in a determined order of the time-relations of our representations. But of how few representations are we able to know the place assigned to them by the law of causality in the chain of causes and effects! Yet we are never embarrassed to distinguish objective from subjective representations: real, from imaginary objects. When asleep, we are unable to make this distinction, for our brain is then isolated from the peripherical nervous system, and thereby from external influences. In

our dreams therefore, we take imaginary for real things, and it is only when we awaken: that is, when our nervous sensibility, and through this the outer world, once more comes within our consciousness, that we become aware of our mistake; still, even in our dreams, so long as they last, the causal law holds good, only an impossible material is often substituted for the usual one. We might almost think that Kant was influenced by Leibnitz in writing the passage we have quoted, however much he differs from him in all the rest of his philosophy; especially if we consider that Leibnitz expresses precisely similar views, when, for instance, he says: "La vérité des choses sensibles ne consiste que dans la liaison des phénomènes, qui doit avoir sa raison, et c'est ce qui les distingue des songes. —— Le vrai Critérion, en matière des objets des sens, est la liaison des phénomènes, qui garantit les vérités de fait, à l'egard des choses sensibles hors de nous."[101]

It is clear that in proving the *à priority* and the necessity of the causal law by the fact that the objective succession of changes is known to us only by means of that law, and that, in so far, causality is a condition for all experience, Kant fell into a very singular error, and one which is indeed so palpable, that the only way we can account for it is, by supposing him to have become so absorbed in the *à priori* part of our knowledge, that he lost sight of what would have been evident to anyone else. The only correct demonstration of the *à priority* of the causal law is given by me in § 21 of the present work. That *à priority* finds its confirmation every moment in the infallible security with which we expect experience to tally with the causal law: that is to say, in the apodeictic certainty we ascribe to it, a certainty which differs from every other founded on induction — the certainty, for instance, of empirically known laws of Nature — in that we can conceive no exception to the causal law anywhere within the world of experience. We can, for instance, *conceive* that in an exceptional case the law of gravitation might cease to act, but not that this could happen without a cause.

Kant and Hume have fallen into opposite errors in their proofs. Hume asserts that all *consequence* is mere *sequence*; whereas Kant affirms that all *sequence* must necessarily be *consequence*. Pure Understanding, it is true, can only conceive *consequence* (causal result), and is no more able to conceive mere *sequence* than to conceive the difference between right and left, which, like sequence, is only to be grasped by means of pure Sensibility. Empirical knowledge of the following of events in Time is, indeed, just as possible as empirical knowledge of juxtaposition of things in

Space (this Kant denies elsewhere), but *the way in which* things follow *upon* one another in general in Time can no more be explained, than the way in which one thing follows *from* another (as the effect of a cause): the former knowledge is given and conditioned by pure Sensibility; the latter, by pure Understanding. But in asserting that knowledge of the objective succession of phenomena can only be attained by means of the causal law, Kant commits the same error with which he reproaches Leibnitz:[102] that of "intellectualising the forms of Sensibility." — My view of succession is the following one. We derive our knowledge of the bare *possibility* of succession from the form of Time, which belongs to pure Sensibility. The succession of real objects, whose form is precisely Time, we know empirically, consequently as *actual*. But it is through the Understanding alone, by means of Causality, that we gain knowledge of the *necessity* of a succession of two states: that is, of a change; and even the fact that we are able to conceive the necessity of a succession at all, proves already that the causal law is not known to us empirically, but given us *à priori*. The Principle of Sufficient Reason is the general expression for the fundamental form of the necessary connection between all our objects, *i.e.* representations, which lies in the innermost depths of our cognitive faculty: it is the form common to all representations, and the only source of the conception of *necessity*, which contains absolutely nothing else in it and no other import, than that of the following of the consequence, when its reason has been established. Now, the reason why this principle determines the order of succession in Time in the class of representations we are now investigating, in which it figures as the law of causality, is, that Time is the form of these representations, therefore the necessary connection appears here as the rule of succession. In other forms of the principle of sufficient reason, the necessary connection it always demands will appear under quite different forms from that of Time, therefore not as succession; still it always retains the character of a necessary connection, by which the identity of the principle under all its forms, or rather the unity of the root of all the laws of which that principle is the common expression, reveals itself.

If Kant's assertion were correct, which I dispute, our only way of knowing the reality of succession would be through its necessity; but this would presuppose an Understanding that embraced all the series of causes and effects at once, consequently an omniscient Understanding. Kant has

burdened the Understanding with an impossibility, merely in order to have less need of Sensibility.

How can we reconcile Kant's assertion that our only means of knowing the objective reality of succession is by the necessity with which effect follows cause, with his other assertion[103] that succession in Time is our only empirical criterion for determining which of two states is cause, and which effect. Who does not see the most obvious circle here?

If we knew objectiveness of succession through Causality, we should never be able to think it otherwise than as Causality, and then it would be nothing else than Causality. For, if it were anything else, it would have other distinctive signs by which to be recognised; now this is just what Kant denies. Accordingly, if Kant were right, we could not say: "This state is the effect of that one, wherefore it follows it;" for following and being an effect, would be one and the same thing, and this proposition a tautology. Besides, if we do away with all distinction between following *upon* and following *from*, we once more yield the point to Hume, who declared all consequence to be mere sequence and therefore denied that distinction likewise.

Kant's proof would, consequently, be reduced to this: that, empirically, we only know *actuality* of succession; but as besides we recognise *necessity* of succession in certain series of occurrences, and even know before all experience that every possible occurrence must have a fixed place in some one of these series, the reality and the *à priority* of the causal law follow as a matter of course, the only correct proof of the latter being the one I have given in § 21 of this work.

Parallel with the Kantian theory: that the causal nexus alone renders objective succession and our knowledge of it possible, there runs another: that coexistence and our knowledge of it are only possible through reciprocity. In the "Critique of Pure Reason" they are presented under the title: "Third Analogy of Experience." Here Kant goes so far as to say that "the co-existence of phenomena, which exercise no reciprocal action on one another, but are separated by a perfectly empty space, could never become an object of possible perception"[104] (which, by the way, would be a proof *à priori* that there is no empty space between the fixed stars), and that "the light which *plays between* our eyes and celestial bodies" — an expression conveying surreptitiously the thought, that this starlight not only acts upon our eyes, but is acted upon by them also— "produces an intercommunity

between us and them, and proves the co-existence of the latter." Now, even empirically, this last assertion is false; since the sight of a fixed star by no means proves its coexistence simultaneously with its spectator, but, at most, its existence some years, nay even some centuries before. Besides, this second Kantian theory stands and falls with the first, only it is far more easily detected; and the nullity of the whole conception of reciprocity has been shown in § 20.

The arguments I have brought forward against Kant's proof may be compared with two previous attacks made on it by Feder,[105] and by G. E. Schulze.[106]

Not without considerable hesitation did I thus venture (in 1813) to attack a theory which had been universally received as a demonstrated truth, is repeated even now in the latest publications,[107] and forms a chief point in the doctrine of one for whose profound wisdom I have the greatest reverence and admiration; one to whom, indeed, I owe so much, that his spirit might truly say to me, in the words of Homer:

Ἀχλὺν δ' αὖ τοι ἀπ' ὀφθαλμῶν ἕλον, ἣ πρὶν ἐπῆεν.[108]

§ 24. *Of the Misapplication of the Law of Causality.*

From the foregoing exposition it follows, that the application of the causal law to anything but *changes* in the material, empirically given world, is an abuse of it. For instance, it is a misapplication to make use of it with reference to physical forces, without which no changes could take place; or to Matter, *on* which they take place; or to the world, to which we must in that case attribute an absolutely objective existence independently of our intellect; indeed in many other cases besides. I refer the reader to what I have said on this subject in my chief work.[109] Such misapplications always arise, partly, through our taking the conception of cause, like many other metaphysical and ethical conceptions, in far *too wide* a sense; partly, through our forgetting that the causal law is certainly a presupposition which we bring with us into the world, by which the perception of things outside us becomes possible; but that, just on that account, we are not authorized in extending beyond the range and independently of our cognitive faculty a principle, which has its origin in the equipment of that faculty, nor in assuming it to hold good as the everlasting order of the universe and of all that exists.

§ 25. *The Time in which a Change takes place.*

As the Principle of Sufficient Reason of Becoming is exclusively applicable to *changes*, we must not omit to mention here, that the ancient philosophers had already raised the question as to the time in which a change takes place, there being no possibility of it taking place during the existence of the preceding state nor after the new one has supervened. Yet, if we assign a special time to it between both states, a body would, during this time, be neither in the first nor in the second state: a dying man, for instance, would be neither alive nor dead; a body neither at rest nor in movement: which would be absurd. The scruples and sophistic subtleties which this question has evoked, may be found collected together in Sextus Empiricus "Adv. Mathem." lib. ix. 267-271, and "Hypat." iii. c. 14; the subject is likewise dealt with by Gellius, l. vi. c. 13 — Plato[110] had disposed somewhat cavalierly of this knotty point, by maintaining that changes take place *suddenly* and occupy *no time at all*; they occur, he says, in the ἐξαίφνης (*in repentino*), which he calls an ἄτοπος φύσις, ἐν χρόνῳ οὐδὲν οὖσα; a strange, timeless existence (which nevertheless comes within Time).

It was accordingly reserved for the perspicacity of Aristotle to clear up this difficult point, which he has done profoundly and exhaustively in the sixth Book of Physics, chap. i.-viii. His proof that no change takes place suddenly (in Plato's ἐξαίφνης), but that each occurs only gradually and therefore occupies a certain time, is based entirely upon the pure, *à priori* intuition of Time and of Space; but it is also very subtle. The pith of this very lengthy demonstration may, however, be reduced to the following propositions. When we say of objects that they limit each other, we mean, that both have their extreme ends in common; therefore only two extended things can be conterminous, never two indivisible ones, for then they would be *one* — *i.e.* only lines, but not mere points, can be conterminous. He then transfers this from Space to Time. As there always remains a line between two points, so there always remains a time between two *nows*; this is the time in which a change takes place — *i.e.* when *one* state is in the first, and *another* in the second, *now*. This time, like every other, is divisible to infinity; consequently, whatever is changing passes through an infinite number of degrees within that time, through which the second state

gradually grows out of that *first* one. — The process may perhaps be made more intelligible by the following explanation. Between two consecutive states the difference of which is perceptible to our senses, there are always several intermediate states, the difference between which is not perceptible to us; because, in order to be sensuously perceptible, the newly arising state must have reached a certain degree of intensity or of magnitude: it is therefore preceded by degrees of lesser intensity or extension, in passing through which it gradually arises. Taken collectively, these are comprised under the name of *change*, and the time occupied by them is called *the time of change*. Now, if we apply this to a body being propelled, the first effect is a certain vibration of its inner parts, which, after communicating the impulse to other parts, breaks out into external motion. — Aristotle infers quite rightly from the infinite divisibility of Time, that everything which fills it, therefore every change, *i.e.* every passage from one state to another, must likewise be susceptible of endless subdivision, so that all that arises, does so in fact by the concourse of an infinite multitude of parts; accordingly its genesis is always gradual, never sudden. From these principles and the consequent gradual arising of each movement, he draws the weighty inference in the last chapter of this Book, that nothing indivisible, no mere *point* can move. And with this conclusion Kant's definition of Matter, as "that which moves in Space," completely harmonizes.

This law of the continuity and gradual taking place of all changes which Aristotle was thus the first to lay down and prove, we find stated three times by Kant: in his "Dissertatio de mundi sensibilis et intelligibilis forma," § 14, in the "Critique of Pure Reason,"[111] and finally in his "Metaphysical First Principles of Natural Science."[112] In all three places his exposition is brief, but also less thorough than that of Aristotle; still, in the main, both entirely agree. We can therefore hardly doubt that, directly or indirectly, Kant must have derived these ideas from Aristotle, though he does not mention him. Aristotle's proposition — οὐκ ἔστι ἀλλήλων ἐχόμενα τὰ νῦν ("the moments of the present are not continuous") — we here find expressed as follows: "between two moments there is always a time," to which may be objected that "even between two centuries there is none; because in Time as in Space, there must always be a pure limit." — Thus Kant, instead of mentioning Aristotle, endeavours in the first and earliest of his three statements to identify the theory he is advancing with Leibnitz' *lex*

continuitatis. If they really were the same, Leibnitz must have derived his from Aristotle. Now Leibnitz[113] first stated this *Loi de la continuité* in a letter to Bayle.[114] There, however, he calls it *Principe de l'ordre général*, and gives under this name a very general, vague, chiefly geometrical argumentation, having no direct bearing on the time of change, which he does not even mention.

CHAPTER V. ON THE SECOND CLASS OF OBJECTS FOR THE SUBJECT AND THE FORM OF THE PRINCIPLE OF SUFFICIENT REASON WHICH PREDOMINATES IN IT.

§ 26. *Explanation of this Class of Objects.*

The only essential distinction between the human race and animals, which from time immemorial has been attributed to a special cognitive faculty peculiar to mankind, called *Reason*, is based upon the fact that man owns a class of representations which is not shared by any animal. These are *conceptions*, therefore *abstract*, as opposed to *intuitive*, representations, from which they are nevertheless derived. The immediate consequence of this is, that animals can neither speak nor laugh; but indirectly all those various, important characteristics which distinguish human from animal life are its consequence. For, through the supervention of abstract representation, motivation has now changed its character. Although human actions result with a necessity no less rigorous than that which rules the actions of animals, yet through this new kind of motivation — so far as here it consists in *thoughts* which render elective decision (*i.e.* a conscious conflict of motives) possible — action with a purpose, with reflection, according to plans and principles, in concert with others, &c. &c., now takes the place of mere impulse given by present, perceptible objects; but by this it gives rise to all that renders human life so rich, so artificial, and so terrible, that man, in this Western Hemisphere, where his skin has become bleached, and where the primitive, true, profound religions of his first home could not follow him, now no longer recognises animals as his brethren, and falsely believes them to differ fundamentally from him, seeking to confirm this illusion by calling them brutes, giving degrading names to the vital functions which they have in common with him, and proclaiming them outlaws; and thus he hardens his heart against that identity of being between them and himself, which is nevertheless constantly obtruding itself upon him.

Still, as we have said, the whole difference lies in this — that, besides the intuitive representations examined in the last chapter, which are shared by animals, other, abstract representations derived from these intuitive ones, are lodged in the human brain, which is chiefly on this account so much

larger than that of animals. Representations of this sort have been called *conceptions*,[115] because each comprehends innumerable individual things in, or rather under, itself, and thus forms a complex.[116] We may also define them as *representations drawn from representations*. For, in forming them, the faculty of abstraction decomposes the complete, intuitive representations described in our last chapter into their component parts, in order to think each of these parts separately as the different qualities of, or relations between, things. By this process, however, the representations necessarily forfeit their perceptibility; just as water, when decomposed, ceases to be fluid and visible. For although each quality thus isolated (abstracted) can quite well be *thought* by itself, it does not at all follow that it can be *perceived* by itself. We form conceptions by dropping a good deal of what is given us in perception, in order to be able to think the rest by itself. To conceive therefore, is to think less than we perceive. If, after considering divers objects of perception, we drop something different belonging to each, yet retain what is the same in all, the result will be the *genus* of that species. The generic conception is accordingly always the conception of every species comprised under it, after deducting all that does not belong to *every* species. Now, as every possible conception may be thought as a *genus*, a conception is always something general, and as such, not perceptible. Every conception has on this account also its *sphere*, as the sum-total[117] of what may be thought under it. The higher we ascend in abstract thought, the more we deduct, the less therefore remains to be thought. The highest, *i.e.* the most general conceptions, are the emptiest and poorest, and at last become mere husks, such as, for instance, being, essence, thing, becoming, &c. &c. — Of what avail, by the way, can philosophical systems be, which are only spun out of conceptions of this sort and have for their substance mere flimsy husks of thoughts like these? They must of necessity be exceedingly empty, poor, and therefore also dreadfully tiresome.

Now as representations, thus sublimated and analysed to form abstract conceptions, have, as we have said, forfeited all perceptibility, they would entirely escape our consciousness, and be of no avail to it for the thinking processes to which they are destined, were they not fixed and retained in our senses by arbitrary signs. These signs are words. In as far as they constitute the contents of dictionaries and therefore of language, words always designate *general* representations, conceptions, never perceptible objects; whereas a lexicon which enumerates individual things, only

contains proper names, not words, and is either a geographical or historical dictionary: that is to say, it enumerates what is separated either by Time or by Space; for, as *my* readers know, Time and Space are the *principium individuationis*. It is only because animals are limited to intuitive representations and incapable of any abstraction — incapable therefore of forming conceptions — that they are without language, even when they are able to articulate words; whereas they understand proper names. That it is this same defect which excludes them from laughter, I have shown in my theory of the ridiculous.[118]

On analyzing a long, continuous speech made by a man of no education, we find in it an abundance of logical forms, clauses, turns of phrase, distinctions, and subtleties of all sorts, correctly expressed by means of grammatical forms with their inflections and constructions, and even with a frequent use of the *sermo obliquus*, of the different moods, &c. &c., all in conformity with rule, which astonishes us, and in which we are forced to recognise an extensive and perfectly coherent knowledge. Still this knowledge has been acquired on the basis of the perceptible world, the reduction of whose whole essence to abstract conceptions is the fundamental business of the Reason, and can only take place by means of language. In learning the use of language therefore, the whole mechanism of Reason — that is, all that is essential in Logic — is brought to our consciousness. Now this can evidently not take place without considerable mental effort and fixed attention, for which the desire to learn gives children the requisite strength. So long as that desire has before it what is really available and necessary, it is vigorous, and it only appears weak when we try to force upon children that which is not suited to their comprehension. Thus even a coarsely educated child, in learning all the turns and subtleties of language, as well through its own conversation as that of others, accomplishes the development of its Reason, and acquires that really concrete Logic, which consists less in logical rules than in the proper application of them; just as the rules of harmony are learnt by persons of musical talent simply by playing the piano, without reading music or studying thorough-bass. — The deaf and dumb alone are excluded from the above-mentioned logical training through the acquirement of speech; therefore they are almost as unreasonable as animals, when they have not been taught to read by the very artificial means specially adapted for their requirements, which takes the place of the natural schooling of Reason.

§ 27. *The Utility of Conceptions.*

The fundamental essence of our Reason or thinking faculty is, as we have seen, the power of abstraction, or the faculty of forming *conceptions*: it is therefore the presence of these in our consciousness which produces such amazing results. That it should be able to do this, rests mainly on the following grounds.

It is just because they contain less than the representations from which they are drawn, that conceptions are easier to deal with than representations; they are, in fact, to these almost as the formula of higher arithmetic to the mental operations which give rise to them and which they represent, or as a logarithm to its number. They only contain just the part required of the many representations from which they are drawn; if instead we were to try to recall those representations themselves by means of the imagination, we should, as it were, have to lug about a load of unessential lumber, which would only embarrass us; whereas, by the help of conceptions, we are enabled to think only those parts and relations of all these representations which are wanted for each individual purpose: so that their employment may be compared to doing away with superfluous luggage, or to working with extracts instead of plants themselves — with quinine, instead of bark. What is properly called *thinking*, in its narrowest sense, is the occupation of the intellect with conceptions: that is, the presence in our consciousness of the class of representations we now have before us. This is also what we call *reflection*: a word which, by a figure of speech borrowed from Optics, expresses at once the derivative and the secondary character of this kind of knowledge. Now it is this thinking, this reflection, which gives man that *deliberation*, which is wanting in animals. For, by enabling him to think many things under one conception, but always only the essential part in each of them, it allows him to drop at his pleasure every kind of distinction, consequently even those of Time and of Space, and thus he acquires the power of embracing in thought, not only the past and the future, but also what is absent; while animals are in every respect strictly bound to the present. This deliberative faculty again is really the root of all those theoretical and practical achievements which give man so great a superiority over animals; first and foremost, of his care for the future while taking the past into consideration; then of his premeditated, systematic, methodical procedure in all undertakings, and therefore of the co-operation

of many persons towards a common end, and, by this, of law, order, the State, &c. &c. — But it is especially in Science that the use of conceptions is important; for they are, properly speaking, its materials. The aims of all the sciences may, indeed, in the last resort, be reduced to knowledge of the particular through the general; now this is only possible by means of the *dictum de omni et nullo*, and this, again, is only possible through the existence of conceptions. Aristotle therefore says: ἄνευ μὲν γὰρ τῶν καθόλου οὐκ ἔστιν ἐπιστήμην λαβεῖν[119] (*absque universalibus enim non datur scientia*). Conceptions are precisely those *universalia*, whose mode of existence formed the argument of the long controversy between the Realists and Nominalists in the Middle Ages.

§ 28. *Representatives of Conceptions. The Faculty of Judgment.*

Conceptions must not be confounded with pictures of the imagination, these being intuitive and complete, therefore individual representations, although they are not called forth by sensuous impressions and do not therefore belong to the complex of experience. Even when used to *represent a conception*, a picture of the imagination (phantasm) ought to be distinguished from a conception. We use phantasms as *representatives of conceptions* when we try to grasp the intuitive representation itself that has given rise to the conception and to make it tally with that conception, which is in all cases impossible; for there is no representation, for instance, of dog in general, colour in general, triangle in general, number in general, nor is there any picture of the imagination which corresponds to these conceptions. Then we evoke the phantasm of some dog or other, which, as a representation, must in all cases be determined: that is, it must have a certain size, shape, colour, &c. &c.; even though the conception represented by it has no such determinations. When we use such *representatives of conceptions* however, we are always conscious that they are not adequate to the conceptions they represent, and that they are full of arbitrary determinations. Towards the end of the first part of his Twelfth Essay on Human Understanding, Hume expresses himself in agreement with this view, as also Rousseau in his “Discours sur l’Origine de l’Inégalité.”[120] Kant’s doctrine, on the contrary, is a totally different one. The matter is one which introspection and clear reflection can alone decide. Each of us must therefore examine himself as to whether he is conscious in his own

conceptions of a “Monogram of Pure Imagination *à priori*;” whether, for instance, when he thinks dog, he is conscious of something *entre chien et loup*; or whether, as I have here explained it, he is either thinking an abstract conception through his Reason, or representing some representative of that conception as a complete picture through his imagination.

All thinking, in a wider sense: that is, all inner activity of the mind in general, necessitates either words or pictures of the imagination: without one or other of these it has nothing to hold by. They are not, however, both necessary at the same time, although they may co-operate to their mutual support. Now, thinking in a narrower sense — that is, abstract reflection by means of words — is either purely logical reasoning, in which case it keeps strictly to its own sphere; or it touches upon the limits of perceptible representations in order to come to an understanding with them, so as to bring that which is given by experience and grasped by perception into connection with abstract conceptions resulting from clear reflection, and thus to gain complete possession of it. In thinking therefore, we seek either for the conception or rule to which a given perception belongs, or for the particular case which proves a given conception or rule. In this quality, thinking is an activity of the *faculty of judgment*, and indeed in the first case a reflective, in the second, a subsuming activity. The faculty of judgment is accordingly the mediator between intuitive and abstract knowledge, or between the Understanding and the Reason. In most men it has merely rudimentary, often even merely nominal existence;[121] they are destined to follow the lead of others, and it is as well not to converse with them more than is necessary.

The true kernel of all knowledge is that reflection which works with the help of intuitive representations; for it goes back to the fountain-head, to the basis of all conceptions. Therefore it generates all really original thoughts, all primary and fundamental views and all inventions, so far as chance had not the largest share in them. *The Understanding* prevails in this sort of thinking, whilst *the Reason* is the chief factor in purely abstract reflection. Certain thoughts which wander about for a long time in our heads, belong to this sort of reflection: thoughts which come and go, now clothed in one kind of intuition, now in another, until they at last become clear, fix themselves in conceptions and find words to express them. Some, indeed, never find words to express them, and these are, unfortunately, the best of all: *quæ voce meliora sunt*, as Apuleius says.

Aristotle, however, went too far in thinking that no reflection is possible without pictures of the imagination. Nevertheless, what he says on this point,[122] οὐδέποτε νοεῖ ἄνευ φαντάσματος ἡ ψυχή (*anima sine phantasmate nunquam intelligit*),[123] and ὅταν θεωρῇ, ἀνάγκη ἅμα φάντασμά τι θεωρεῖν (*qui contemplatur, necesse est, una cum phantasmate contempletur*),[124] and again, νοεῖν οὐκ ἔστι ἄνευ φαντάσματος (*fieri non potest, ut sine phantasmate quidquam intelligatur*),[125] — made a strong impression upon the thinkers of the fifteenth and sixteenth centuries, who therefore frequently and emphatically repeat what he says. Pico della Mirandola,[126] for instance, says: *Necesse est, eum, qui ratiocinatur et intelligit, phantasmata speculari*; — Melanchthon[127] says: *Oportet intelligentem phantasmata speculari*; — and Jord. Brunus[128] says, *dicit Aristoteles: oportet scire volentem, phantasmata speculari*. Pomponatius[129] expresses himself in the same sense. — On the whole, all that can be affirmed is, that every true and primary notion, every genuine philosophic theorem even, must have some sort of intuitive view for its innermost kernel or root. This, though something momentary[130] and single, subsequently imparts life and spirit to the whole analysis, however exhaustive it may be, — just as one drop of the right reagent suffices to tinge a whole solution with the colour of the precipitate which it causes. When an analysis has a kernel of this sort, it is like a bank note issued by a firm which has ready money wherewith to back it; whereas every other analysis proceeding from mere combinations of abstract conceptions, resembles a bank note which is issued by a firm which has nothing but other paper obligations to back it with. All mere rational talk thus renders the result of given conceptions clearer, but does not, strictly speaking, bring anything new to light. It might therefore be left to each individual to do himself, instead of filling whole volumes every day.

§ 29. *Principle of Sufficient Reason of Knowing.*

But, even in a narrower sense, thinking does not consist in the bare presence of abstract conceptions in our consciousness, but rather in connecting or separating two or more of these conceptions under sundry restrictions and modifications which Logic indicates in the Theory of Judgments. A relation of this sort between conceptions distinctly thought and expressed we call a *judgment*. Now, with reference to these judgments, the Principle of Sufficient Reason here once more holds good, yet in a widely different form

from that which has been explained in the preceding chapter; for here it appears as the Principle of Sufficient Reason of Knowing, *principium rationis sufficientis cognoscendi*. As such, it asserts that if a *judgment* is to express *knowledge* of any kind, it must have a sufficient reason: in virtue of which quality it then receives the predicate *true*. Thus *truth* is the reference of a judgment to something different from itself, called its reason or ground, which reason, as we shall presently see, itself admits of a considerable variety of kinds. As, however, this reason is invariably a something upon which the judgment rests, the German term for it, viz., *Grund*, is not ill chosen. In Latin, and in all languages of Latin origin, the word by which a reason of knowledge is designated, is the same as that used for the faculty of Reason (*ratiocinatio*): both are called *ratio*, *la ragione*, *la razon*, *la raison*, *the reason*. From this it is evident, that attaining knowledge of the reasons of judgments had been recognised as Reason's highest function, its business κατ' ἐξοχήν. Now, these grounds upon which a judgment may rest, may be divided into *four* different kinds, and the truth obtained by that judgment will correspondingly differ. They are stated in the following paragraph.

§ 30. *Logical Truth.*

A judgment may have for its reason another judgment; in this case it has *logical* or *formal* truth. Whether it has material truth also, remains an open question and depends on whether the judgment on which it rests has material truth, or whether the series of judgments on which it is founded leads to a judgment which has material truth, or not. This founding of a judgment upon another judgment always originates in a comparison between them which takes place either directly, by mere conversion or contraposition, or by adding a third judgment, and then the truth of the judgment we are founding becomes evident through their mutual relation. This operation is the complete *syllogism*. It is brought about either by the opposition or by the subsumption of conceptions. As the syllogism, which is the founding of one judgment upon another by means of a third, never has to do with anything but judgments; and as judgments are only combinations of conceptions, and conceptions again are the exclusive object of our Reason: syllogizing has been rightly called Reason's special function. The whole syllogistic science, in fact, is nothing but the sum-total

of the rules for applying the principle of sufficient reason to the mutual relations of judgments; consequently it is the canon of *logical truth*.

Judgments, whose truth becomes evident through the four well-known laws of thinking, must likewise be regarded as based upon other judgments; for these four laws are themselves precisely judgments, from which follows the truth of those other judgments. For instance, the judgment: "A triangle is a space enclosed within three lines," has for its last reason the Principle of Identity, that is to say, the thought expressed by that principle. The judgment, "No body is without extension," has for its last reason the Principle of Contradiction. This again, "Every judgment is either true or untrue," has for its last reason the Principle of the Excluded Middle; and finally, "No one can admit anything to be true without knowing why," has for its last reason the Principle of Sufficient Reason of Knowing. In the general employment of our Reason, we do not, it is true, before admitting them to be true, reduce judgments which follow from the four laws of thinking to their last reasons, as premisses; for most men are even ignorant of the very existence of these abstract laws. The dependence of such judgments upon them, as their premisses, is however no more diminished by this, than the dependence of the first judgment upon the second, as its premiss, is diminished by the fact, that it is not at all necessary for the principle, "all bodies incline towards the centre of the earth," to be present in the consciousness of any one who says, "this body will fall if its support is removed." That in Logic, therefore, *intrinsic truth* should hitherto have been attributed to all judgments founded exclusively on the four laws of thinking: that is to say, that these judgments should have been pronounced *directly true*, and that this *intrinsic logical truth* should have been distinguished from *extrinsic logical truth*, as attributed to all judgments which have another judgment for their reason, I cannot approve. Every truth is the reference of a judgment to something *outside* of it, and the term *intrinsic truth* is a contradiction.

§ 31. *Empirical Truth.*

A judgment may be founded upon a representation of the first class, *i.e.* a perception by means of the senses, consequently on experience. In this case it has *material truth*, and moreover, if the judgment is founded *immediately* on experience, this truth is *empirical truth*.

When we say, “A judgment has *material truth*,” we mean on the whole, that its conceptions are connected, separated, limited, according to the requirements of the intuitive representations through which it is inferred. To attain knowledge of this, is the direct function of the *faculty of judgment*, as the mediator between the intuitive and the abstract or discursive faculty of knowing — in other words, between the Understanding and the Reason.

§ 32. *Transcendental Truth.*

The *forms* of intuitive, empirical knowledge which lie within the Understanding and pure Sensibility may, as conditions of all possible experience, be the grounds of a judgment, which is in that case synthetical *à priori*. As nevertheless this kind of judgment has material truth, its truth is *transcendental*; because the judgment is based not only on experience, but on the conditions of all possible experience lying within us. For it is determined precisely by that which determines experience itself: namely, either by the forms of Space and of Time perceived by us *à priori*, or by the causal law, known to us *à priori*. Propositions such as: two straight lines do not include a space; nothing happens without a cause; matter can neither come into being nor perish; 3 × 7 = 21, are examples of this kind of judgment. The whole of pure Mathematics, and no less my tables of the *Prædicabilia à priori*,[131] as well as most of Kant’s theorems in his “Metaphysische Anfangsgründe der Naturwissenschaft,” may, properly speaking, be adduced in corroboration of this kind of truth.

§ 33. *Metalogical Truth.*

Lastly, a judgment may be founded on the formal conditions of all thinking, which are contained in the Reason; and in this case its truth is of a kind which seems to me best defined as *metalogical truth*. This expression has nothing at all to do with the “Metalogicus” written by Johannes Sarisberriensis in the twelfth century, for he declares in his prologue, “*quia Logicæ suscepi patrocinium, Metalogicus inscriptus est liber*,” and never makes use of the word again. There are only four metalogically true judgments of this sort, which were discovered long ago by induction, and called the laws of all thinking; although entire uniformity of opinion as to their expression and even as to their number has not yet been arrived at,

whereas all agree perfectly as to what they are on the whole meant to indicate. They are the following: —

1. A subject is equal to the sum total of its predicates, or a = a.

2. No predicate can be attributed and denied to a subject at the same time, or a = -a = o.

3. One of two opposite, contradictory predicates must belong to every subject.

4. Truth is the reference of a judgment to something outside of it, as its sufficient reason.

It is by means of a kind of reflection which I am inclined to call Reason's self-examination, that we know that these judgments express the conditions of all thinking, and therefore have these conditions for their reason. For, by the fruitlessness of its endeavours to think in opposition to these laws, our Reason acknowledges them to be the conditions of all possible thinking: we then find out, that it is just as impossible to think in opposition to them, as it is to move the members of our body in a contrary direction to their joints. If it were possible for the subject to know itself, these laws would be known to us *immediately*, and we should not need to try experiments with them on objects, *i.e.* representations. In this respect it is just the same with the reasons of judgments which have transcendental truth; for they do not either come into our consciousness immediately, but only in *concreto*, by means of objects, *i.e.* of representations. In endeavouring, for instance, to conceive a change without a preceding cause, or a passing into or out of being of Matter, we become aware that it is impossible; moreover we recognise this impossibility to be an objective one, although its root lies in our intellect: for we could not otherwise bring it to consciousness in a subjective way. There is, on the whole, a strong likeness and connection between transcendental and metalogical truths, which shows that they spring from a common root. In this chapter we see the Principle of Sufficient Reason chiefly as metalogical truth, whereas in the last it appeared as transcendental truth and in the next one it will again be seen as transcendental truth under another form. In the present treatise I am taking special pains, precisely on this account, to establish the Principle of Sufficient Reason as a judgment having a fourfold reason; by which I do not mean four different reasons leading contingently to the same judgment, but one reason presenting itself under a fourfold aspect: and this is what I call its Fourfold Root. The other three metalogical truths so strongly resemble

one another, that in considering them one is almost necessarily induced to search for their common expression, as I have done in the Ninth Chapter of the Second Volume of my chief work. On the other hand, they differ considerably from the Principle of Sufficient Reason. If we were to seek an analogue for the three other metalogical truths among transcendental truths, the one I should choose would be this: Substance, I mean Matter, is permanent.

§ 34. *Reason.*

As the class of representations I have dealt with in this chapter belongs exclusively to Man, and as all that distinguishes human life so forcibly from that of animals and confers so great a superiority on man, is, as we have shown, based upon his faculty for these representations, this faculty evidently and unquestionably constitutes that Reason, which from time immemorial has been reputed the prerogative of mankind. Likewise all that has been considered by all nations and in all times explicitly as the work or manifestation of the Reason, of the λόγος, λόγιμον, λογιστικόν, *ratio*, *la ragione*, *la razon*, *la raison*, *reason*, may evidently also be reduced to what is only possible for abstract, discursive, reflective, mediate knowledge, conditioned by words, and not for mere intuitive, immediate, sensuous knowledge, which belongs to animals also. Cicero rightly places *ratio et oratio* together,[132] and describes them as *quæ docendo, discendo, communicando, disceptando, judicando, conciliat inter se homines*, &c. &c., and[133] *rationem dico, et, si placet, pluribus verbis, mentem, consilium, cogitationem, prudentiam*. And[134] *ratio, qua una præstamus beluis, per quam conjectura valemus, argumentamur, refellimus, disserimus, conficimus aliquid, concludimus*. But, in all ages and countries, philosophers have invariably expressed themselves in this sense with respect to the Reason, even to Kant himself, who still defines it as the faculty for principles and for inference; although it cannot be denied that he first gave rise to the distorted views which followed. In my principal work,[135] and also in the Fundamental Problems of Ethics, I have spoken at great length about the agreement of all philosophers on this point, as well as about the true nature of Reason, as opposed to the distorted conceptions for which we have to thank the professors of philosophy of this century. I need

not therefore repeat what has already been said there, and shall limit myself to the following considerations.

Our professors of philosophy have thought fit to do away with the name which had hitherto been given to that faculty of thinking and pondering by means of reflection and conceptions, which distinguishes man from animals, which necessitates language while it qualifies us for its use, with which all human deliberation and all human achievements hang together, and which had therefore always been viewed in this light and understood in this sense by all nations and even by all philosophers. In defiance of all sound taste and custom, our professors decided that this faculty should henceforth be called *Understanding* instead of *Reason*, and that all that is derived from it should be named *intelligent* instead of *rational*, which, of course, had a strange, awkward ring about it, like a discordant tone in music. For in all ages and countries the words *understanding*, *intellectus*, *acumen*, *perspicacia*, *sagacitas*, &c. &c., had been used to denote the more intuitive faculty described in our last chapter; and its results, which differ specifically from those of Reason here in question, have always been called *intelligent*, *sagacious*, *clever*, &c. &c. *Intelligent* and *rational* were accordingly always distinguished one from the other, as manifestations of two entirely and widely different mental faculties. Our professional philosophers could not, however, take this into account; their policy required the sacrifice, and in such cases the cry is: “Move on, truth; for we have higher, well-defined aims in view! Make way for us, truth, *in majorem Dei gloriam*, as thou hast long ago learnt to do! Is it thou who givest fees and pensions? Move on, truth, move on; betake thyself to merit and crouch in the corner!” The fact was, they wanted Reason’s place and name for a faculty of their own creation and fabrication, or to speak more correctly and honestly, for a completely fictitious faculty, destined to help them out of the straits to which Kant had reduced them; a faculty for direct, metaphysical knowledge: that is to say, one which transcends all possible experience, is able to grasp the world of things in themselves and their relations, and is therefore, before all, consciousness of God (*Gottesbewusstsein*): that is, it knows God the Lord immediately, construes *à priori* the way in which he has created the Universe, or, should this sound too trivial, the way in which he has produced it out of himself, or to a certain degree generated it by some more or less necessary vital process, or again — as the most convenient proceeding, however comical it may appear — simply

"dismissed" it, according to the custom of sovereigns at the end of an audience, and left it to get upon its legs by itself and walk away wherever it liked. Nothing less than the impudence of a scribbler of nonsense like Hegel, could, it is true, be found to venture upon this last step. Yet it is tom-foolery like this which, largely amplified, has filled hundreds of volumes for the last fifty years under the name of cognitions of Reason (*Vernunfterkenntnisse*), and forms the argument of so many works called philosophical by their authors, and scientific by others — one would think ironically — this expression being even repeated to satiety. *Reason*, to which all this wisdom is falsely and audaciously imputed, is pronounced to be a "supersensuous faculty," or a faculty "for ideas;" in short, an oracular power lying within us, designed directly for Metaphysics. During the last half-century, however, there has been considerable discrepancy of opinion among the adepts as to the way in which all these supersensuous wonders are perceived. According to the most audacious, Reason has a direct intuition of the Absolute, or even *ad libitum* of the Infinite and of its evolutions towards the Finite. Others, somewhat less bold, opine that its mode of receiving this information partakes rather of audition than of vision; since it does not exactly see, but merely *hears* (*vernimmt*), what is going on in "cloud-cuckoo-land" (νεφελοκοκκυγία), and then honestly transmits what it has thus received to the Understanding, to be worked up into text-books. According to a pun of Jacobi's, even the German name for Reason, "*Vernunft*," is derived from this pretended "*Vernehmen*;" whereas it evidently comes from that "*Vernehmen*" which is conveyed by language and conditioned by Reason, and by which the distinct perception of words and their meaning is designated, as opposed to mere sensuous hearing which animals have also. This miserable *jeu de mots* nevertheless continues, after half a century, to find favour; it passes for a serious thought, nay even for a proof, and has been repeated over and over again. The most modest among the adepts again assert, that Reason neither sees nor hears, therefore it receives neither a vision nor a report of all these wonders, and has a mere vague *Ahndung*, or misgiving of them; but then they drop the *d*, by which the word (*Ahnung*) acquires a peculiar touch of silliness, which, backed up as it is by the sheepish look of the apostle for the time being of this wisdom, cannot fail to gain it entrance.

My readers know that I only admit the word *idea* in its primitive, that is Platonic, sense, and that I have treated this point at length and exhaustively

in the Third Book of my chief work. The French and English, on the other hand, certainly attach a very commonplace, but quite clear and definite meaning to the word *idée*, or *idea*; whereas the Germans lose their heads as soon as they hear the word *Ideen*;[136] all presence of mind abandons them, and they feel as if they were about to ascend in a balloon. Here therefore was a field of action for our adepts in intellectual intuition; so the most impudent of them, the notorious *charlatan* Hegel, without more ado, called his theory of the universe and of all things "*Die Idee*," and in this of course all thought that they had something to lay hold of. Still, if we inquire into the nature of these *ideas* for which Reason is pronounced to be the faculty, without letting ourselves be put out of countenance, the explanation usually given is an empty, high-flown, confused verbiage, in set periods of such length, that if the reader does not fall asleep before he has half read it, he will find himself bewildered rather than enlightened at the end; nay, he may even have a suspicion that these ideas are very like chimæras. Meanwhile, should anyone show a desire to know more about this sort of ideas, he will have all kinds of things served up to him. Now it will be the chief subjects of the theses of Scholasticism — I allude here to the representations of God, of an immortal Soul, of a real, objectively existent World and its laws — which Kant himself has unfortunately called Ideas of Reason, erroneously and unjustifiably, as I have shown in my Critique of his philosophy, yet merely with a view to proving the utter impossibility of demonstrating them and their want of all theoretical authority. Then again it will be, as a variation, only God, Freedom, and Immortality; at other times it will be the Absolute, whose acquaintance we have already made in § 20, as the Cosmological Proof, forced to travel incognito; or the Infinite as opposed to the Finite; for, on the whole, the German reader is disposed to content himself with such empty talk as this, without perceiving that the only clear thought he can get out of it is, 'that which has an end' and 'that which has none.' 'The Good, the True, and the Beautiful,' moreover, stand high in favour with the sentimental and tender-hearted as pretended *ideas*, though they are really only three very wide and abstract conceptions, because they are extracted from a multitude of things and relations; wherefore, like many other such *abstracta*, they are exceedingly empty. As regards their contents, I have shown above (§ 29) that Truth is a quality belonging exclusively to judgments: that is, a logical quality; and as to the other two *abstracta*, I refer my readers partly to § 65 of the first volume, partly to the

entire Third Book of my chief work. If, nevertheless, a very solemn and mysterious air is assumed and the eyebrows are raised up to the wig whenever these three meagre *abstracta* are mentioned, young people may easily be induced to believe that something peculiar and inexpressible lies behind them, which entitles them to be called *ideas*, and harnessed to the triumphal car of this would-be metaphysical Reason.

When therefore we are told, that we possess a faculty for direct, material (*i.e.*, not only formal, but substantial), supersensuous knowledge, (that is, a knowledge which transcends all possible experience), a faculty specially designed for metaphysical insight, and inherent in us for this purpose — I must take the liberty to call this a downright lie. For the slightest candid self-examination will suffice to convince us that absolutely no such faculty resides within us. The result at which all honest, competent, authoritative thinkers have arrived in the course of ages, moreover, tallies exactly with my assertion. It is as follows: All that is innate in the whole of our cognitive faculty, all that is therefore *à priori* and independent of experience, is strictly limited to the *formal* part of knowledge: that is, to the consciousness of the peculiar functions of the intellect and of the only way in which they can possibly act; but in order to give material knowledge, these functions one and all require material from outside. Within us therefore lie the forms of external, objective perception: Time and Space, and then the law of Causality — as a mere form of the Understanding which enables it to construct the objective, corporeal world — finally, the formal part of abstract knowledge: this last is deposited and treated of in *Logic*, which our forefathers therefore rightly called the *Theory of Reason*. But this very Logic teaches us also, that the *conceptions* which constitute those judgments and conclusions to which all logical laws refer, must look to *intuitive* knowledge for their *material* and their *content*; just as the Understanding, which creates *this intuitive knowledge*, looks to sensation for the material which gives content to its *à priori* forms.

Thus all that is *material* in our knowledge: that is to say, all that cannot be reduced to subjective *form*, to individual mode of activity, to functions of our intellect, — its whole *material* therefore, — comes from outside; that is, in the last resort, from the objective perception of the corporeal world, which has its origin in sensation. Now it is this intuitive and, so far as material content is concerned, empirical knowledge, which *Reason — real*

Reason — works up into conceptions, which it fixes sensuously by means of words; these conceptions then supply the materials for its endless combinations through judgments and conclusions, which constitute the weft of our thought-world. *Reason* therefore has absolutely no *material*, but merely a *formal*, content, and this is the object-matter of Logic, which consequently contains only forms and rules for thinking operations. In reflecting, Reason is absolutely forced to take its material contents from outside, *i.e.*, from the intuitive representations which the Understanding has created. Its functions are exercised on them, first of all, in forming *conceptions*, by dropping some of the various qualities of things while retaining others, which are then connected together to a conception. Representations, however, forfeit their capacity for being intuitively perceived by this process, while they become easier to deal with, as has already been shown. It is therefore in this, and in this alone, that the efficiency of Reason consists; whereas it can never supply *material content from its own resources*. — It has nothing but forms: its nature is feminine; it only conceives, but does not generate. It is not by mere chance that the Reason is feminine in all Latin, as well as Teutonic, languages; whereas the Understanding is invariably masculine.

In using such expressions as 'sound Reason teaches this,' or 'Reason should control passion,' we by no means imply that Reason furnishes material knowledge out of its own resources; but rather do we point to the results of rational reflection, that is, to logical inference from principles which abstract knowledge has gradually gathered from experience and by which we obtain a clear and comprehensive view, not only of what is empirically necessary, and may therefore, the case occurring, be foreseen, but even of the reasons and consequences of our own deeds also. *Reasonable* or *rational* is everywhere synonymous with *consistent* or *logical*, and conversely; for Logic is only Reason's natural procedure itself, expressed in a system of rules; therefore these expressions (rational and logical) stand in the same relation to one another as theory and practice. Exactly in this same sense too, when we speak of a reasonable conduct, we mean by it one which is quite consistent, one therefore which proceeds from general conceptions, and is not determined by the transitory impression of the moment. By this, however, the morality of such conduct is in no wise determined: it may be good or bad indifferently. Detailed explanations of all this are to be found in my "Critique of Kant's Philosophy,"[137] and also in my

"Fundamental Problems of Ethics."[138] Notions derived from *pure Reason* are, lastly, those which have their source in the *formal* part, whether intuitive or reflective, of our cognitive faculty; those, consequently, which we are able to bring to our consciousness *à priori*, that is, without the help of experience. They are invariably based upon principles which have transcendental or metalogical truth.

A Reason, on the other hand, which supplies material knowledge primarily out of its own resources and conveys positive information transcending the sphere of possible experience; a Reason which, in order to do this, must necessarily contain *innate ideas*, is a pure fiction, invented by our professional philosophers and a product of the terror with which Kant's Critique of Pure Reason has inspired them. I wonder now, whether these gentlemen know a certain Locke and whether they have ever read his works? Perhaps they may have done so in times long gone by, cursorily and superficially, while looking down complacently on this great thinker from the heights of their own conscious superiority: may be, too, in some inferior German translation; for I do not yet see that the knowledge of modern languages has increased in proportion to the deplorable decrease in that of ancient ones. How could time besides be found for such old croakers as Locke, when even a real, thorough knowledge of Kant's Philosophy at present hardly exists excepting in a very few, very old heads? The youth of the generation now at its maturity had of course to be spent in the study of "Hegel's gigantic mind," of the "sublime Schleiermacher," and of the "acute Herbart." Alas! alas! the great mischief in academical hero-worship of this sort, and in the glorification of university celebrities by worthy colleagues in office or hopeful aspirants to it, is precisely, that ordinary intellects — Nature's mere manufactured ware — are presented to honest credulous youths of immature judgment, as master minds, exceptions and ornaments of mankind. The students forthwith throw all their energies into the barren study of the endless, insipid scribblings of such mediocrities, thus wasting the short, invaluable period allotted to them for higher education, instead of using it to attain the sound information they might have found in the works of those extremely rare, genuine, truly exceptional thinkers, *nantes in gurgite vasto*, who only rise to the surface every now and then in the course of ages, because Nature produced but one of each kind, and then "destroyed the mould." For this generation also those great minds might have had life, had our youth not been cheated out of its share in their wisdom by these

exceedingly pernicious extollers of mediocrity, members of the vast league and brotherhood of mediocrities, which is as flourishing to-day as it ever was and still hoists its flag as high as it can in persistent antagonism to all that is great and genuine, as humiliating to its members. Thanks to them, our age has declined to so low an ebb, that Kant's Philosophy, which it took our fathers years of study, of serious application and of strenuous effort to understand, has again become foreign to the present generation, which stands before it like ὄνος πρὸς λύραν, at times attacking it coarsely and clumsily — as barbarians throw stones at the statue of some Greek god which is foreign to them. Now, as this is the case, I feel it incumbent upon me to advise all champions of a Reason that perceives, comprehends, and knows directly — in short, that supplies material knowledge out of its own resources — to read, as something new to them, the *First Book* of Locke's work, which has been celebrated throughout the world for the last hundred and fifty years, and in it especially to peruse §§ 21-26 of the Third Chapter, expressly directed against all innate notions. For although Locke goes too far in denying all innate truths, inasmuch as he extends his denial even to our *formal* knowledge — a point in which he has been brilliantly rectified by Kant — he is nevertheless perfectly and undeniably right with reference to all *material* knowledge: that is, all knowledge which gives substance.

I have already said in my Ethics what I must nevertheless repeat here, because, as the Spanish proverb says, "*No hay peor sordo que quien no quiere oir*" (None so deaf as those who will not hear): namely, that if Reason were a faculty specially designed for Metaphysics, a faculty which supplied the material of knowledge and could reveal that which transcends all possible experience, the same harmony would necessarily reign between men on metaphysical and religious subjects — for they are identical — as on mathematical ones, and those who differed in opinion from the rest would simply be looked upon as not quite right in their mind. Now exactly the contrary takes place, for on no subject are men so completely at variance with one another as upon these. Ever since men first began to think, philosophical systems have opposed and combated each other everywhere; they are, in fact, often diametrically contrary to one another. Ever since men first began to believe (which is still longer), religions have fought against one another with fire and sword, with excommunication and cannons. But in times when faith was most ardent, it was not the lunatic asylum, but the Inquisition, with all its paraphernalia, which awaited

individual heretics. Here again, therefore, experience flatly and categorically contradicts the false assertion, that Reason is a faculty for direct metaphysical knowledge, or, to speak more clearly, of inspiration from above. Surely it is high time that severe judgment should be passed upon this Reason, since, *horribile dictu*, so lame, so palpable a falsehood continues after half a century to be hawked about all over Germany, wandering year by year from the professors' chair to the students' bench, and from bench to chair, and has actually found a few simpletons, even in France, willing to believe in it, and carry it about in that country also. Here, however, French *bon-sens* will very soon send *la raison transcendentale* about its business.

But where was this falsehood originally hatched? How did the fiction first come into the world? I am bound to confess that it was first originated by Kant's Practical Reason with its Categorical Imperative. For when this Practical Reason had once been admitted, nothing further was needed than the addition of a second, no less sovereign Theoretical Reason, as its counterpart, or twin-sister: a Reason which proclaims metaphysical truths *ex tripode*. I have described the brilliant success of this invention in my Fundamental Problems of Ethics[139] to which work I refer my reader. Now, although I grant that Kant first gave rise to this false assumption, I am, nevertheless, bound to add, that those who want to dance are not long in finding a piper. For it is surely as though a curse lay on mankind, causing them, in virtue of a natural affinity for all that is corrupt and bad, to prefer and hold up to admiration the inferior, not to say downright defective, portions of the works of eminent minds, while the really admirable parts are tolerated as merely accessory. Very few in our time know wherein the peculiar depth and true grandeur of Kant's philosophy lies; for his works have necessarily ceased to be comprehended since they have ceased to be studied. In fact, they are now only cursorily read, for historical purposes, by those who are under the delusion that philosophy has advanced, not to say begun, since Kant. We soon perceive therefore, that in spite of all their talk about Kantian philosophy, these people really know nothing of it but the husk, the mere outer envelope, and that if perchance they may here or there have caught up a stray sentence or brought away a rough sketch of it, they have never penetrated to the depths of its meaning and spirit. People of this sort have always been chiefly attracted, in Kant's Philosophy, first of all by the Antinomies, on account of their oddity, but still more by his Practical

Reason with its Categorical Imperative, nay even by the Moral Theory he placed on the top of it, though with this last he was never in earnest; for a theoretical dogma which has only practical validity, is very like the wooden guns we allow our children to handle without fear of danger: properly speaking, it belongs to the same category as: "Wash my skin, but without wetting it." Now, as regards the Categorical Imperative, Kant never asserted it as a fact, but, on the contrary, protests repeatedly against this being done; he merely served it up as the result of an exceedingly curious combination of thoughts, because he stood in need of a sheet-anchor for morality. Our professors of philosophy, however, never sifted the matter to the bottom, so that it seems as if no one before me had ever thoroughly investigated it. Instead of this, they made all haste to bring the Categorical Imperative into credit as a firmly established fact, calling it in their purism "the moral law" — which, by the way, always reminds me of Bürger's "Mam'zelle Larègle;" indeed, they have made out of it something as massive as the stone tables of Moses, whose place it entirely takes, for them. Now in my Essay upon the Fundament of Morality, I have brought this same Practical Reason with its Categorical Imperative under the anatomical knife, and proved so clearly and conclusively that they never had any life or truth, that I should like to see the man who can refute me with reasons, and so help the Categorical Imperative honestly on its legs again. Meanwhile, our professors of philosophy do not allow themselves to be put out of countenance by this. They can no more dispense with their "moral law of practical Reason," as a convenient *deus ex machina* on which to found their morality, than with Free Will: both are essential points in their old woman's philosophy. No matter if I have made an end of both, since, for them, both continue to exist, like deceased sovereigns who for political reasons are occasionally allowed to continue reigning for a few days after their death. These worthies simply pursue their tactics of old against my merciless demolition of those two antiquated fictions: silence, silence; and so they glide past noiselessly, feigning ignorance, to make the public believe that I and the like of me are not worth listening to. Well, to be sure, their philosophical calling comes to them from the ministry, while mine only comes from Nature. True, we may at last perhaps discover that these heroes act upon the same principle as that idealistic bird, the ostrich, which imagines that by closing its eyes it does away with the huntsman. Ah well! we must bide our time; if the public can only be brought to take up

meantime with the barren twaddle, the unbearably tiresome repetitions, the arbitrary constructions of the Absolute, and the infant-school morality of these gentlemen — say, till I am dead and they can trim up my works as they like — we shall then see.

Morgen habe denn das Rechte
Seine Freunde wohlgesinnet,
Wenn nur heute noch das Schlechte
Vollen Platz und Gunst gewinnet.
Göthe, *West-Oestlicher Divan*.

But do these gentlemen know what time of day it is? A long predicted epoch has set in; the church is beginning to totter, nay it totters already to such a degree, that it is doubtful whether it will ever be able to recover its centre of gravity; for faith is lost. The light of revelation, like other lights, requires a certain amount of darkness as an indispensable condition. The number of those who have been unfitted for belief by a certain degree and extent of knowledge, is already very large. Of this we have evident signs in the general diffusion of that shallow Rationalism which is showing its bulldog face daily more and more overtly. It quietly sets to work to measure those profound mysteries of Christianity over which centuries have brooded and disputed with its draper's ell, and thinks itself wondrous wise withal. It is, however, the very quintessence of Christianity, the dogma of Original Sin, which these shallow-brained Rationalists have especially singled out for a laughing-stock; precisely because nothing seems clearer or more certain to them, than that existence should begin for each of us with our birth: nothing therefore so impossible as that we can have come into the world already burdened with guilt. How acute! And just as in times of prevailing poverty and neglect, wolves begin to make their appearance in villages; so does Materialism, ever lying in wait, under these circumstances lift up its head and come to the front hand in hand with Bestialism, its companion, which some call Humanism. Our thirst after knowledge augments with our incapacity for belief. There comes a boiling-point in the scale of all intellectual development, at which all faith, all revelation, and all authority evaporate, and Man claims the right to judge for himself; the right, not only to be taught, but to be convinced. The leading-strings of his infancy have fallen off, and henceforth he demands leave to walk alone. Yet his craving for Metaphysics can no more be extinguished than any physical want. Then it is, that the desire for philosophy becomes serious and that

mankind invokes the spirits of all the genuine thinkers who have issued from its ranks. Then, too, empty verbiage and the impotent endeavours of emasculated intellects no longer suffice; the want of a serious philosophy is felt, having other aims in view than fees and salaries, and caring little therefore whether it meets the approbation of cabinet-ministers, or councillors, whether it serves the purposes of this or that religious faction, or not; a philosophy which, on the contrary, clearly shows that it has a very different mission in view from that of procuring a livelihood for the poor in spirit.

But I return to my argument. By means of an amplification which only needed a little audacity, a *theoretical* oracle had been added to the *practical* oracle with which Kant had wrongly endowed Reason. The credit of this invention is no doubt due to F. H. Jacobi, from whom the professional philosophers joyfully and thankfully received the precious gift, as a means to help them out of the straits to which Kant had reduced them. That cool, calm, deliberate Reason, which Kant had criticized so mercilessly, was henceforth degraded to *Understanding* and known by this name; while Reason was supposed to denote an entirely imaginary, fictitious faculty, admitting us, as it were, to a little window overlooking the superlunar, nay, the supernatural world, through which all those truths are handed to us ready cut and dried, concerning which old-fashioned, honest, reflective Reason had for ages vainly argued and contended. And it is on such a mere product of the imagination, such a completely fictitious Reason as this, that German sham philosophy has been based for the last fifty years; first, as the free construction and projection of the absolute *Ego* and the emanation from it of the *non-Ego*; then, as the intellectual intuition of absolute identity or indifference, and its evolutions to Nature; or again, as the arising of God out of his dark depths or bottomless pit[140] *à la* Jakob Böhme; lastly, as the pure, self-thinking, absolute Idea, the scene of the ballet-dance of the self-moving conceptions — still, at the same time, always as immediate apprehension (*Vernehmen*) of the Divine, the supersensuous, the Deity, verity, beauty and as many other "-ties" as may be desired, or even as a mere vague presentiment[141] of all these wonders. — So this is Reason, is it? Oh no, it is simply a farce, of which our professors of philosophy, who are sorely perplexed by Kant's serious critiques, avail themselves in order to pass off the subjects of the established religion of their country somehow or other, *per fas aut nefas*, for the results of philosophy.

For it behoves all professorial philosophy, before all things, to establish beyond doubt, and to give a philosophical basis to, the doctrine, that there is a God, Creator, and Ruler of the Universe, a personal, consequently individual, Being, endowed with Understanding and Will, who has created the world out of nothing, and who rules it with sublime wisdom, power and goodness. This obligation, however, places our professors of philosophy in an awkward position with respect to serious philosophy. For Kant had appeared and the Critique of Pure Reason, was written more than sixty years ago, the result being, that of all the proofs of the existence of God which had been brought forward during the Christian ages, and which may be reduced to three which alone are possible, none are able to accomplish the desired end. Nay, the impossibility of any such proof, and with it the impossibility of all speculative theology, is shown at length *à priori* and not in the empty verbiage or Hegelian jargon now in fashion, which may be made to mean anything one likes, but quite seriously and honestly, in the good old-fashioned way; wherefore, however little it may have been to the taste of many people, nothing cogent could be brought forward in reply to it for the last sixty years, and the proofs of the existence of God have in consequence lost all credit, and are no longer in use. Our professors of philosophy have even begun to look down upon them and treat them with decided contempt, as ridiculous and superfluous attempts to demonstrate what was self-evident. Ho! ho! what a pity this was not found out sooner! How much trouble might have been spared in searching whole centuries for these proofs, and how needless it would have been for Kant to bring the whole weight of his Critique of Reason to bear upon and crush them! Some folks, will no doubt be reminded by this contempt of the fox with the sour grapes. But those who wish to see a slight specimen of it will find a particularly characteristic one in Schelling's "Philosophische Schriften," vol. i., 1809, p. 152. Now, whilst others were consoling themselves with Kant's assertion, that it is just as impossible to prove the non-existence, as the existence, of God — as if, forsooth, the old wag did not know that *affirmanti incumbit probatio* — Jacobi's admirable invention came to the rescue of our perplexed professors, and granted German *savants* of this century a peculiar sort of Reason that had never been known or heard of before.

Yet all these artifices were quite unnecessary. For the impossibility of proving the existence of God by no means interferes with that existence,

since it rests in unshakeable security on a much firmer basis. It is indeed a matter of revelation, and this is besides all the more certain, because that revelation was exclusively vouchsafed to a single people, called, on this account, the chosen people of God. This is made evident by the fact, that the notion of God, as personal Ruler and Creator of the world, ordaining everything for the best, is to be found in no other religion but the Jewish, and the two faiths derived from it, which might consequently in a wider sense be called Jewish sects. We find no trace of such a notion in any other religion, ancient or modern. For surely no one would dream of confounding this Creator God Almighty with the Hindoo Brahm, which is living in me, in you, in my horse, in your dog — or even with Brahma, who is born and dies to make way for other Brahmas, and to whom moreover the production of the world is imputed as sin and guilt[142] — least of all with beguiled Saturn's voluptuous son, to whom Prometheus, defiant, prophesies his downfall. But if we finally direct our attention towards the religion which numbers most followers, and in this respect may therefore be said to rank foremost: that is, Buddhism, we can no longer shut our eyes to the fact that it is as decidedly and explicitly atheistic, as it is idealistic and ascetic; and this moreover to such a degree, that its priests express the greatest abhorrence of the doctrine of pure Theism whenever it is brought to their notice. Therefore, in a treatise handed to a Catholic bishop by the High Priest of the Buddhists at Ava,[143] the doctrine "that there is a Being who has created the world and all things, and who alone is worthy of worship," is counted among the six damnable heresies.[144] This is entirely corroborated by I. J. Schmidt, a most excellent and learned authority, whom I consider as having undoubtedly the deepest knowledge of Buddhism of any European *savant*, and who, in his work "Upon the connection between Gnostic doctrines and Buddhism," p. 9, says: —

"In the writings of the Buddhists not a trace is to be found of any positive indication of a Supreme Being as the principle of Creation. Whenever this subject presents itself consistently in the course of argument, it seems, indeed, to be intentionally evaded." And again: "The system of Buddhism knows of no eternal, uncreated, one and only Being, having existed before Time and created all that is visible and invisible. This idea is quite foreign to Buddhism, and not a trace of it is to be found in Buddhist works. And just as little mention do we find of Creation. True, the visible Universe is not without a beginning, but it *arose* out of empty Space,

according to consistent, immutable, natural laws. We should however err, were we to assume that anything — call it Fate or Nature — is regarded or revered by the Buddhists as a divine principle; on the contrary, it is just this very development of empty Space, this precipitate from it or this division into countless parts, this Matter thus arising, which constitutes the Evil of *Jirtintschi*, or of the Universe in its inner and outer relations, out of which sprang *Ortschilang*, or continuous change according to immutable laws, which the same Evil had established." Then again:[145] "The expression *Creation* is foreign to Buddhism, which only knows *Cosmogony*;" and, "We must comprehend that no idea of a creation of divine origin is compatible with their system." I could bring forward a hundred corroborative passages like these; but will limit myself to one more, which I quote on account of its popular and official character. The third volume of a very instructive Buddhist work, "Mahavansi, Raja-ratnacari, and Raja-Vali,"[146] contains a translation of the interrogatories to which the High Priests of the five chief Pagodas were separately and successively subjected by the Dutch Governor of Ceylon about the year 1766. It is exceedingly amusing to see the contrast between the interlocutors, who have the greatest difficulty in understanding one another's meaning. In conformity with the doctrines of their faith, these priests, who are penetrated with love and compassion for all living beings, not excepting even Dutch Governors, spare no pains to satisfy him by their answers. But the artless, naïve Atheism of these priests, whose piety extends even to practising continence, soon comes into conflict with the deep convictions founded on Judaism, imbibed by the Governor in his infancy. This faith has become a second nature for him; he cannot in the least understand that these priests are not Theists, therefore he constantly returns to his inquiries after a Supreme Being, asking them who created the world, and so forth. Whereupon they answer that there can be no higher being than Buddha Shakia-Muni, the Victorious and the Perfect, who, though a king's son by birth, voluntarily lived the life of a beggar, and preached to the end his sublime doctrine, for the Redemption of mankind, and for our salvation from the misery of constant renascence. They hold that the world has not been made by anyone,[147] that it is self-created, that Nature spreads it out, and draws it in again; but that it is that, which existing, does not exist: that it is the necessary accompaniment of renascence, and that renascence is the result of our sinful conduct, &c. &c. &c. I mention such facts as these chiefly on account of the really scandalous

way in which German *savants* still universally persist, even to the present day, in looking upon Religion and Theism as identical and synonymous; whereas Religion is, in fact, to Theism as the genus to the single species, and Judaism and Theism are alone identical. For this reason we stigmatize as heathen all nations who are neither Jews, Christians, nor Mahometans. Christians are even taxed by Mahometans and Jews with the impurity of their Theism, because of the dogma of the Trinity. For, whatever may be said to the contrary, Christianity has Indian blood in its veins, therefore it constantly tends to free itself from Judaism. The Critique of Pure Reason is the most serious attack that has ever been made upon Theism — and this is why our professors of philosophy have been in such a hurry to set Kant aside; but had that work appeared in any country where Buddhism prevailed, it would simply have been regarded as an edifying treatise intended to refute heresy more thoroughly by a salutary confirmation of the orthodox doctrine of Idealism — that is, the doctrine of the merely apparent existence of the world, as it presents itself to our senses. Even the two other religions which coexist with Buddhism in China — those of Taotsee and of Confucius — are just as Atheistic as Buddhism itself; wherefore the missionaries have never been able to translate the first verse of the Pentateuch into Chinese, because there is no word in the language for God and Creation. Even the missionary Gützlaff, in his "History of the Chinese Empire," p. 18, has the honesty to say: "It is extraordinary that none of the (Chinese) philosophers ever soared high enough to reach the knowledge of a Creator and Lord of the Universe, although they possessed the Light of Nature in full measure." J. F. Davis likewise quotes a passage, which is quite in accordance with this, from Milne's Preface to his translation of the Shing-yu, where in speaking of that work, he says that we may see from it "that the bare Light of Nature, as it is called, even when aided by all the light of Pagan philosophy, is totally incapable of leading men to the knowledge and worship of the true God." All this confirms the fact that revelation is the sole foundation on which Theism rests; indeed, it must be so, unless revelation is to be superfluous. This is a good opportunity for observing that the word Atheism itself implies a surreptitious assumption, since it takes Theism for granted as a matter of course. It would be more honest to say Non-Judaism instead of Atheism, and Non-Jew instead of Atheist.

Now as, according to the above, the existence of God belongs to revelation, by which it is firmly established, it has no need whatever of human authentication. Philosophy, however, is properly speaking only an idle, superfluous attempt to let Reason — that is, the human power of thinking, reflecting, deliberating — once in a while, try its own powers unassisted, as a child is now and then allowed to run alone on a lawn and try its strength without leading-strings, just to see what will come of it. Tests and experiments of this kind we call *speculation*; and it lies in the nature of the matter that it should, for once, leave all authority, human or divine, out of consideration, ignore it, and go its own way in search of the most sublime, most important truths. Now, if on this basis it should arrive at the very same results as those mentioned above, to which Kant had come, speculation has no right on that account to cast all honesty and conscience forthwith aside, and take to by-ways, in order somehow or other to get back to the domain of Judaism, as its *conditio sine qua non*; it ought rather henceforth to seek truth quite honestly and simply by any road that may happen to lie open before it, but never to allow any other light than that of Reason to guide it: thus advancing calmly and confidently, like one at work in his vocation, without concern as to where that road may lead.

If our professors of philosophy put a different construction on the matter, and hold that they cannot eat their bread in honour, so long as they have not reinstalled God Almighty on his throne — as if, forsooth, he stood in need of *them* — this already accounts for their not relishing my writings, and explains why I am not the man for them; for I certainly do not deal in this sort of article, nor have I the newest reports to communicate about the Almighty every Leipzig fair-time, as they have.

CHAPTER VI. ON THE THIRD CLASS OF OBJECTS FOR THE SUBJECT AND THAT FORM OF THE PRINCIPLE OF SUFFICIENT REASON WHICH PREDOMINATES IN IT.

§ 35. *Explanation of this Class of Objects.*

It is the formal part of complete representations — that is to say, the intuitions given us *à priori* of the forms of the outer and inner sense, *i.e.* of Space and of Time — which constitutes the Third Class of Objects for our representative faculty.

As pure intuitions, these forms are objects for the faculty of representation by themselves and apart from complete representations and from the determinations of being empty or filled which these representations first add to them; since even pure points and pure lines cannot be brought to sensuous perception, but are only *à priori* intuitions, just as the infinite expansion and the infinite divisibility of Space and of Time are exclusively objects of pure intuition and foreign to empirical perception. That which distinguishes the third class of representations, in which Space and Time are *pure intuitions*, from the first class, in which they are *sensuously* (and moreover conjointly) *perceived*, is Matter, which I have therefore defined, on the one hand, as the perceptibility of Space and Time, on the other, as objectified Causality.

The form of Causality, on the contrary, which belongs to the Understanding, is not separately and by itself an object for our faculty of representation, nor have we consciousness of it, until it is connected with what is material in our knowledge.

§ 36. *Principle of the Sufficient Reason of Being.*

Space and Time are so constituted, that all their parts stand in mutual relation, so that each of them conditions and is conditioned by another. We call this relation in Space, *position*; in Time, *succession*. These relations are peculiar ones, differing entirely from all other possible relations of our representations; neither the Understanding nor the Reason are therefore able to grasp them by means of mere conceptions, and pure intuition *à priori* alone makes them intelligible to us; for it is impossible by mere conceptions

to explain clearly what is meant by above and below, right and left, behind and before, before and after. Kant rightly confirms this by the assertion, that the distinction between our right and left glove cannot be made intelligible in any other way than by intuition. Now, the law by which the divisions of Space and of Time determine one another reciprocally with reference to these relations (position and succession) is what I call the *Principle of the Sufficient Reason of Being, principium rationis sufficientis essendi*. I have already given an example of this relation in § 15, by which I have shown, through the connection between the sides and angles of a triangle, that this relation is not only quite different from that between cause and effect, but also from that between reason of knowledge and consequent; wherefore here the condition may be called *Reason of Being*, *ratio essendi*. The insight into such a *reason of being* can, of course, become a reason of knowing: just as the insight into the law of causality and its application to a particular case is the reason of knowledge of the effect; but this in no way annuls the complete distinction between Reason of Being, Reason of Becoming, and Reason of Knowing. It often happens, that what according to *one* form of our principle is *consequence*, is, according to another, *reason*. The rising of the quicksilver in a thermometer, for instance, is the *consequence* of increased heat according to the law of causality, while according to the principle of the sufficient reason of knowing it is the *reason*, the ground of knowledge, of the increased heat and also of the judgment by which this is asserted.

§ 37. *Reason of Being in Space.*

The position of each division of Space towards any other, say of any given line — and this is equally applicable to planes, bodies, and points — determines also absolutely its totally different position with reference to any other possible line; so that the latter position stands to the former in the relation of the consequent to its reason. As the position of this given line towards any other possible line likewise determines its position towards all the others, and as therefore the position of the first two lines is itself determined by all the others, it is immaterial which we consider as being first determined and determining the others, *i.e.* which particular one we regard as *ratio* and which others as *rationata*. This is so, because in Space there is no succession; for it is precisely by uniting Space and Time to form

the collective representation of the complex of experience, that the representation of coexistence arises. Thus an analogue to so-called reciprocity prevails everywhere in the Reason of Being in Space, as we shall see in § 48, where I enter more fully into the reciprocity of reasons. Now, as every line is determined by all the others just as much as it determines them, it is arbitrary to consider any line merely as determining and not as being determined, and the position of each towards any other admits the question as to its position with reference to some other line, which second position necessarily determines the first and makes it that which it is. It is therefore just as impossible to find an end *a parte ante* in the series of links in the chain of Reasons of Being as in that of Reasons of Becoming, nor can we find any *a parte post* either, because of the infinity of Space and of the lines possible within Space. All possible relative spaces are figures, because they are limited; and all these figures have their Reason of Being in one another, because they are conterminous. The *series rationum essendi* in Space therefore, like the *series rationum fiendi*, proceeds *in infinitum*; and moreover not only in a single direction, like the latter, but in all directions.

Nothing of all this can be proved; for the truth of these principles is transcendental, they being directly founded upon the intuition of Space given us *à priori*.

§ 38. *Reason of being in Time. Arithmetic.*

Every instant in Time is conditioned by the preceding one. The Sufficient Reason of Being, as the law of consequence, is so simple here, because Time has only one dimension, therefore it admits of no multiplicity of relations. Each instant is conditioned by its predecessor; we can only reach it through that predecessor: only so far as this *was* and has elapsed, does the present one exist. All counting rests upon this nexus of the divisions of Time, numbers only serving to mark the single steps in the succession; upon it therefore rests all arithmetic likewise, which teaches absolutely nothing but methodical abbreviations of numeration. Each number pre-supposes its predecessors as the reasons of its being: we can only reach the number *ten* by passing through all the preceding numbers, and it is only in virtue of this insight that I know, that where ten are, there also are eight, six, four.

§ 39. *Geometry.*

The whole science of Geometry likewise rests upon the nexus of the position of the divisions of Space. It would, accordingly, be an insight into that nexus; only such an insight being, as we have already said, impossible by means of mere conceptions, or indeed in any other way than by intuition, every geometrical proposition would have to be brought back to sensuous intuition, and the proof would simply consist in making the particular nexus in question clear; nothing more could be done. Nevertheless we find Geometry treated quite differently. Euclid's Twelve Axioms are alone held to be based upon mere intuition, and even of these only the Ninth, Eleventh, and Twelfth are properly speaking admitted to be founded upon different, separate intuitions; while the rest are supposed to be founded upon the knowledge that in science we do not, as in experience, deal with real things existing for themselves side by side, and susceptible of endless variety, but on the contrary with conceptions, and in Mathematics with *normal intuitions*, i.e. figures and numbers, whose laws are binding for all experience, and which therefore combine the comprehensiveness of the conception with the complete definiteness of the single representation. For although, as intuitive representations, they are throughout determined with complete precision — no room being left in *this* way by anything remaining undetermined — still they are general, because they are the bare forms of all phenomena, and, as such, applicable to all real objects to which such forms belong. What Plato says of his Ideas would therefore, even in Geometry, hold good of these normal intuitions, just as well as of conceptions, *i.e.* that two cannot be exactly similar, for then they would be but one.[148] This would, I say, be applicable also to normal intuitions in Geometry, if it were not that, as exclusively spacial objects, these differ from one another in mere juxtaposition, that is, in place. Plato had long ago remarked this, as we are told by Aristotle:[149] ἔτι δὲ, παρὰ τὰ αἰσθητὰ καὶ τὰ εἴδη, τὰ μαθηματικὰ τῶν πραγμάτων εἶναί φησι μεταξύ, διαφέροντα τῶν μὲν αἰσθητῶν τῷ ἀΐδια καὶ ἀκίνητα εἶναι, τῶν δὲ είδῶν τῷ τὰ μὲν πόλλ' ἄττα ὅμοια εἶναι, τὸ δὲ εἶδος αὐτὸ ἓν ἕκαστον μόνον (*item, præter sensibilia et species, mathematica rerum ait media esse, a sensibilibus quidem differentia eo, quod perpetua et immobilia sunt, a speciebus vero eo, quod illorum quidem multa quœdam similia sunt, species vero ipsa unaquœque sola*). Now the mere knowledge that such a difference of place does not annul the rest of the identity, might surely, it seems to me,

supersede the other nine axioms, and would, I think, be better suited to the nature of science, whose aim is knowledge of the particular through the general, than the statement of nine separate axioms all based upon the same insight. Moreover, what Aristotle says: ἐν τούτοις ἡ ἰσότης ἑνότης (*in illis æqualitas unitas est*)[150] then becomes applicable to geometrical figures.

But with reference to the normal intuitions in Time, *i.e.* to numbers, even this distinction of juxtaposition no longer exists. Here, as with conceptions, absolutely nothing but the *identitas indiscernibilium* remains: for there is but one five and one seven. And in this we may perhaps also find a reason why 7 + 5 = 12 is a synthetical proposition *à priori*, founded upon intuition, as Kant profoundly discovered, and not an identical one, as it is called by Herder in his "Metakritik". 12 = 12 is an identical proposition.

In Geometry, it is therefore only in dealing with axioms that we appeal to intuition. All the other theorems are demonstrated: that is to say, a reason of knowing is given, the truth of which everyone is bound to acknowledge. The logical truth of the theorem is thus shown, but not its transcendental truth (v. §§ 30 and 32), which, as it lies in the reason of *being* and not in the reason of *knowing*, never can become evident excepting by means of intuition. This explains *why* this sort of geometrical demonstration, while it no doubt conveys the conviction that the theorem which has been demonstrated is true, nevertheless gives no insight as to why that which it asserts is what it is. In other words, we have not found its Reason of Being; but the desire to find it is usually then thoroughly roused. For proof by indicating the reason of knowledge only effects conviction (*convictio*), not knowledge (*cognitio*): therefore it might perhaps be more correctly called *elenchus* than *demonstratio*. This is why, in most cases, therefore, it leaves behind it that disagreeable feeling which is given by all want of insight, when perceived; and here, the want of knowledge *why* a thing is as it is, makes itself all the more keenly felt, because of the certainty just attained, *that* it is as it is. This impression is very much like the feeling we have, when something has been conjured into or out of our pocket, and we cannot conceive how. The reason of knowing which, in such demonstrations as these, is given without the reason of being, resembles certain physical theories, which present the phenomenon without being able to indicate its cause: for instance, Leidenfrost's experiment, inasmuch as it succeeds also

in a platina crucible; whereas the reason of being of a geometrical proposition which is discovered by intuition, like every knowledge we acquire, produces satisfaction. When once the reason of being is found, we base our conviction of the truth of the theorem upon that reason alone, and no longer upon the reason of knowing given us by the demonstration. Let us, for instance, take the sixth proposition of the first Book of Euclid: —

"If two angles of a triangle are equal, the sides also which subtend, or are opposite to, the equal angles shall be equal to one another." (See fig. 3.)

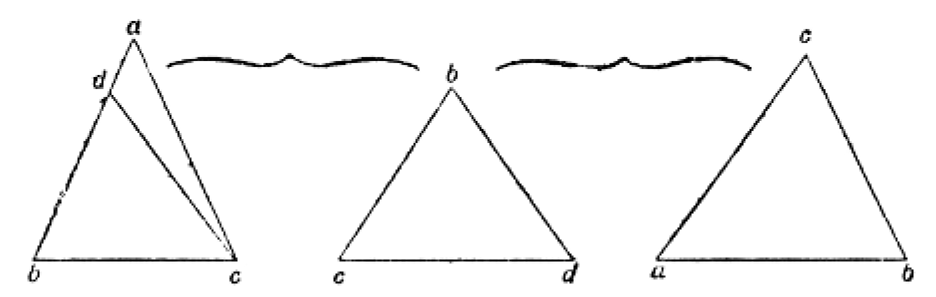

Fig. 3.

Which Euclid demonstrates as follows: —

"Let *a b c* be a triangle having the angle *a b c* equal to the angle *a c b*, then the side *a c* must be equal to the side *a b* also.

"For, if side *a b* be not equal to side *a c*, one of them is greater than the other. Let *a b* be greater than *a c*; and from *b a* cut off *b d* equal to *c a*, and draw *d c*. Then, in the triangles *d b c*, *a b c*, because *d b* is equal to *a c*, and *b c* is common to both triangles, the two sides *d b* and *b c* are equal to the two sides *a c*, *a b*, each to each; and the angle *d b c* is equal to the angle *a c b*, therefore the base *d c* is equal to the base *a b*, and the triangle *d b c* is equal to the triangle *a b c*, the less triangle equal to the greater, — which is absurd. Therefore *a b* is not unequal to *a c*, that is, *a b* is equal to *a c*."

Now, in this demonstration we have a reason of knowing for the truth of the proposition. But who bases his conviction of that geometrical truth upon this proof? Do we not rather base our conviction upon the reason of being, which we know intuitively, and according to which (by a necessity which admits of no further demonstration, but only of evidence through intuition) two lines drawn from both extreme ends of another line, and inclining equally towards each other, can only meet at a point which is equally distant from both extremities; since the two arising angles are properly but one, to which the oppositeness of position gives the appearance of being two;

wherefore there is no reason why the lines should meet at any point nearer to the one end than to the other.

It is the knowledge of the reason of being which shows us the necessary consequence of the conditioned from its condition — in this instance, the lateral equality from the angular equality — that is, it shows their connection; whereas the reason of knowing only shows their coexistence. Nay, we might even maintain that the usual method of proving merely convinces us of their coexistence in the actual figure given us as an example, but by no means that they are always coexistent; for, as the necessary connection is not shown, the conviction we acquire of this truth rests simply upon induction, and is based upon the fact, that we find it is so in every figure we make. The reason of being is certainly not as evident in all cases as it is in simple theorems like this 6th one of Euclid; still I am persuaded that it might be brought to evidence in every theorem, however complicated, and that the proposition can always be reduced to some such simple intuition. Besides, we are all just as conscious *à priori* of the necessity of such a reason of being for each relation of Space, as we are of the necessity of a cause for each change. In complicated theorems it will, of course, be very difficult to show that reason of being; and this is not the place for difficult geometrical researches. Therefore, to make my meaning somewhat clearer, I will now try to bring back to its reason of being a moderately complicated proposition, in which nevertheless that reason is not immediately evident. Passing over the intermediate theorems, I take the 16th:

"In every triangle in which one side has been produced, the exterior angle is greater than either of the interior opposite angles."

This Euclid demonstrates in the following manner (see fig. 4): —

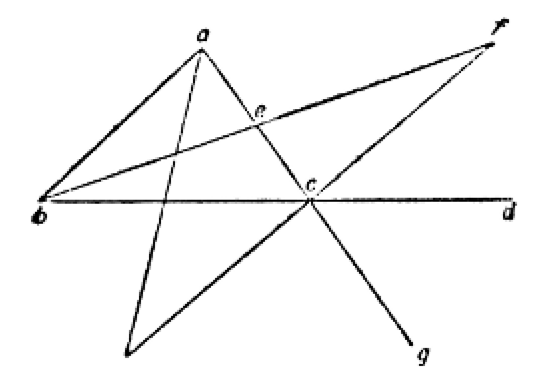

Fig. 4.

"Let *a b c* be a triangle; and let the side *b c* be produced to *d*; then the exterior angle *a c d* shall be greater than either of the interior opposite angles *b a c* or *c b a*. Bisect the side *a c* at *e*, and join *b e*; produce *b e* to *f*, making *e f* equal to *e b*, and join *f c*. Produce *a c* to *g*. Because *a e* is equal to *e c*, and *b e* to *e f*; the two sides *a e*, *e b*, are equal to the two sides *c e*, *e f*, each to each; and the angle *a e b* is equal to the angle *c e f*, because they are opposite vertical angles; therefore the base *a b* is equal to the base *c f*, and the triangle *a e b* is equal to the triangle *c e f*, and the remaining angles of one triangle to the remaining angles of the other, each to each, to which the equal sides are opposite; therefore the angle *b a e* is equal to the angle *e c f*. But the angle *e c d* is greater than the angle *e c f*. Therefore the angle *a c d* is greater than the angle *a b c*."

"In the same manner, if the side *b c* be bisected, and the side *a c* be produced to *g*, it may be demonstrated that the angle *b c g*, that is, the opposite vertical angle *a c d* is greater than the angle *a b c*."

My demonstration of the same proposition would be as follows (see fig. 5): —

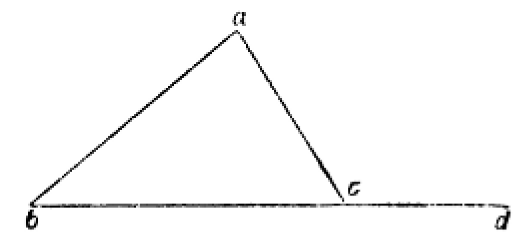

Fig. 5.

For the angle *b a c* to be even equal to, let alone greater than, the angle *a c d*, the line *b a* toward *c a* would have to lie in the same direction as *b d* (for this is precisely what is meant by equality of the angles), *i.e.*, it must be parallel with *b d*; that is to say, *b a* and *b d* must never meet; but in order to form a triangle they must meet (reason of being), and must thus do the contrary of that which would be required for the angle *b a c* to be of the same size as the angle *a c d*.

For the angle *a b c* to be even equal to, let alone greater than, the angle *a c d*, line *b a* must lie in the same direction towards *b d* as *a c* (for this is what is meant by equality of the angles), *i.e.*, it must be parallel with *a c*, that is to say, *b a* and *a c* must never meet; but in order to form a triangle *b*

a and *a c* must meet and must thus do the contrary of that which would be required for the angle *a b c* to be of the same size as *a c d*.

By all this I do not mean to suggest the introduction of a new method of mathematical demonstration, nor the substitution of my own proof for that of Euclid, for which its whole nature unfits it, as well as the fact that it presupposes the conception of parallel lines, which in Euclid comes much later. I merely wished to show what the reason of being is, and wherein lies the difference between it and the reason of knowing, which latter only effects *convictio*, a thing that differs entirely from insight into the reason of being. The fact that Geometry only aims at effecting *convictio*, and that this, as I have said, leaves behind it a disagreeable impression, but gives no insight into the reason of being — which insight, like all knowledge, is satisfactory and pleasing — may perhaps be one of the reasons for the great dislike which many otherwise eminent heads have for mathematics.

I cannot resist again giving fig. 6, although it has already been presented elsewhere; because the mere sight of it without words conveys ten times more persuasion of the truth of the Pythagorean theorem than Euclid's mouse-trap demonstration.

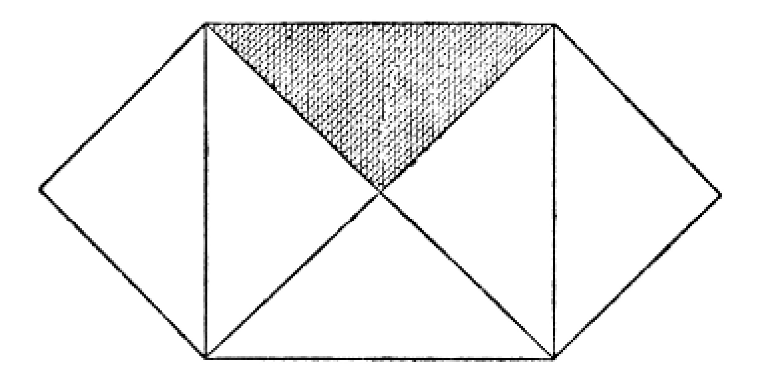

Fig. 6.

Those readers for whom this chapter may have a special interest will find the subject of it more fully treated in my chief work, "Die Welt als Wille und Vorstellung," vol. i. § 15; vol. ii. chap. 13.

CHAPTER VII. ON THE FOURTH CLASS OF OBJECTS FOR THE SUBJECT, AND THE FORM OF THE PRINCIPLE OF SUFFICIENT REASON WHICH PREDOMINATES IN IT.

§ 40. *General Explanation.*

The last Class of Objects for our representative faculty which remains to be examined is a peculiar but highly important one. It comprises but *one* object for each individual: that is, the immediate object of the inner sense, the *Subject in volition*, which is Object for the Knowing Subject; wherefore it manifests itself in Time alone, never in Space, and as we shall see, even in Time under an important restriction.

§ 41. *Subject of Knowledge and Object.*

All knowledge presupposes Subject and Object. Even self-consciousness (*Selbstbewusstsein*) therefore is not absolutely simple, but, like our consciousness of all other things (*i.e.*, the faculty of perception), it is subdivided into that which is known and that which knows. Now, that which is known manifests itself absolutely and exclusively as *Will*.

The Subject accordingly knows itself exclusively as *willing*, but not as *knowing*. For the *ego* which represents, never can itself become representation or Object, since it conditions all representations as their necessary correlate; rather may the following beautiful passage from the Sacred Upanishad be applied to it: *Id videndum non est: omnia videt; et id audiendum non est: omnia audit; sciendum non est: omnia scit: et intelligendum, non est: omnia intelligit. Præter id, videns, et sciens, et audiens, et intelligens ens aliud non est.*[151]

There can therefore be no *knowledge of knowing*, because this would imply separation of the Subject from knowing, while it nevertheless knew that knowing — which is impossible.

My answer to the objection, “I not only know, but know also that I know,” would be, “Your knowing that you know only differs in words from your knowing. ‘I know that I know’ means nothing more than ‘I know,’ and this again, unless it is further determined, means nothing more than ‘*ego*.’ If your knowing and your knowing that you know are two different things,

just try to separate them, and first to know without knowing that you know, then to know that you know without this knowledge being at the same time knowing." No doubt, by leaving all *special* knowing out of the question, we may at last arrive at the proposition "*I know*" — the last abstraction we are able to make; but this proposition is identical with "*Objects exist for me*," and this again is identical with "*I am Subject*," in which nothing more is contained than in the bare word "*I*."

Now, it may still be asked how the various cognitive faculties belonging to the Subject, such as Sensibility, Understanding, Reason, are known to us, if we do not know the Subject. It is not through our knowing having become an Object for us that these faculties are known to us, for then there would not be so many conflicting judgments concerning them; they are inferred rather, or more correctly, they are general expressions for the established classes of representations which, at all times, have been more or less clearly distinguished in those cognitive faculties. But, with reference to the necessary correlate of these representations as their condition, *i.e.*, the Subject, these faculties are abstracted from them (the representations), and stand consequently towards the classes of representations in precisely the same relation as the Subject in general towards the Object in general. Now, just as the Object is at once posited with the Subject (for the word itself would otherwise have no meaning), and conversely, as the Subject is at once posited with the Object — so that being the Subject means exactly as much as having an Object, and being an Object means the same thing as being known by the Subject — so likewise, when an Object is assumed as being determined *in any particular way*, do we also assume that the Subject *knows precisely in that particular way*. So far therefore it is immaterial whether we say that Objects have such and such peculiar inherent determinations, or that the Subject knows in such and such ways. It is indifferent whether we say that Objects are divided into such and such classes, or that such and such different cognitive faculties are peculiar to the Subject. In that singular compound of depth and superficiality, Aristotle, are to be found traces even of insight into this truth, and indeed the critical philosophy lies in embryo in his works. He says:[152] ἡ ψυχὴ τὰ ὄντα πώς ἐστι πάντα (anima quammodo est universa, quæ sunt). And again: ὁ νοῦς ἐστι εἶδος είδῶν, *i.e.*, the understanding is the form of forms, καὶ ἡ αἴσθησις εἶδος αίσθητῶν, and sensibility the form of sensuous objects. Accordingly,

it is all one whether we say, “sensibility and understanding are no more;” or, “the world is at an end.” It comes to the same thing whether we say, “There are no conceptions,” or “Reason is gone and animals alone remain.”

The dispute between Realism and Idealism, which appeared for the last time in the dispute between the Dogmatists and Kantians, or between Ontology and Metaphysics on the one hand and Transcendental Æsthetic and Transcendental Logic on the other, arose out of the misapprehension of this relation and was based upon its misapprehension with reference to the First and Third Classes of representations as established by me, just as the mediæval dispute between Realists and Nominalists rested upon the misapprehension of this relation with reference to the Second Class.

§ 42. *The Subject of Volition.*

According to what has preceded, the Subject of knowledge can never be known; it can never become Object or representation. Nevertheless, as we have not only an outer self-knowledge (in sensuous perception), but an inner one also; and as, on the other hand, every knowledge, by its very nature, presupposes a knower and a known, what is known within us as such, is not the knower, but the willer, the Subject of Volition: the Will. Starting from knowledge, we may assert that “I know” is an analytical, “I will,” on the contrary, a synthetical, and moreover an *à posteriori* proposition, that is, it is given by experience — in this case by inner experience (*i.e.*, in Time alone). In so far therefore the Subject of volition would be an Object for us. Introspection always shows us to ourselves as *willing*. In this *willing*, however, there are numerous degrees, from the faintest wish to passion, and I have often shown[153] that not only all our emotions, but even all those movements of our inner man, which are subsumed under the wide conception of feeling, are states of the will.

Now, the identity of the willing with the knowing Subject, in virtue of which the word “I” includes and designates both, is the *nodus*[154] of the Universe, and therefore inexplicable. For we can only comprehend relations between Objects; but two Objects never can be one, excepting as parts of a whole. Here, where the Subject is in question, the rules by which we know Objects are no longer applicable, and actual identity of the knower with what is known as willing — that is, of Subject and Object — is *immediately given*. Now, whoever has clearly realized the utter impossibility of

explaining this identity, will surely concur with me in calling it the miracle κατ’ ἐξοχήν.

Just as the Understanding is the subjective correlate to our First Class of representations, the Reason to the Second, and pure Sensibility to the Third, so do we find that the correlate to this Fourth Class is the inner sense, or Self-consciousness in general.

§ 43. *Willing. The Law of Motives (Motivation).*

It is just because the willing Subject is immediately given in self-consciousness, that we are unable further to define or to describe what willing is; properly speaking, it is the most direct knowledge we have, nay, one whose immediateness must finally throw light upon every other knowledge, as being very mediate.

At every resolution that we take ourselves, or that we see others take, we deem ourselves justified in asking, why? That is, we assume that something must have previously occurred, from which this resolution has resulted, and we call this something its reason, or, more correctly, the motive of the action which now follows. Without such a reason or motive, the action is just as inconceivable for us, as the movement of a lifeless body without being pushed or pulled. Motives therefore belong to causes, and have also been already numbered and characterized among them in § 20, as the third form of Causality. But all Causality is only the form of the Principle of Sufficient Reason in the First Class of Objects: that is, in the corporeal world given us in external perception. There it forms the link which connects changes one with another, the cause being that which, coming from outside, conditions each occurrence. The inner nature of such occurrences on the contrary continues to be a mystery for us: for we always remain on the outside. We certainly see this cause necessarily produce that effect; but we do not learn how it is actually enabled to do so, or what is going on inside. Thus we see mechanical, physical, chemical effects, as well as those brought about by *stimuli*, in each instance follow from their respective causes without on that account ever completely understanding the process, the essential part of which remains a mystery for us; so we attribute it to qualities of bodies, to forces of Nature, or to vital energy, which, however, are all *qualitates occultæ*. Nor should we be at all better off as to comprehension of the movements and actions of animals and of

human beings, which would also appear to us as induced in some unaccountable way by their causes (motives), were it not that here we are granted an insight into the inward part of the process; we know, that is, by our own inward experience, that this is an act of the will called forth by the motive, which consists in a mere representation. Thus the effect produced by the motive, unlike that produced by all other causes, is not only known by us from outside, in a merely indirect way, but at the same time from inside, quite directly, and therefore according to its whole mode of action. Here we stand as it were behind the scenes, and learn the secret of the process by which cause produces effect in its most inward nature; for here our knowledge comes to us through a totally different channel and in a totally different way. From this results the important proposition: *The action of motives (motivation) is causality seen from within*. Here accordingly causality presents itself in quite a different way, in quite a different medium, and for quite another kind of knowledge; therefore it must now be exhibited as a special and peculiar form of our principle, which consequently here presents itself as the Principle of the Sufficient Reason of Acting, *principium rationis sufficientis agendi*, or, more briefly, as the *Law of Motives (Law of Motivation)*.

As a clue to my philosophy in general, I here add, that this Fourth Class of Objects for the Subject, that is, the one object contained in it, the *will* which we apprehend within us, stands in the same relation towards the First Class as the law of motives towards the law of causality, as I have established it in § 20. This truth is the corner-stone of my whole Metaphysic.

As to the way in which, and the necessity with which, motives act, and as to the dependence of their action upon empirical, individual character, and even upon individual capacity for knowledge, &c. &c., I refer my readers to my Prize-essay on the Freedom of the Will, in which I have treated all this more fully.

§ 44. *Influence of the Will over the Intellect.*

It is not upon causality proper, but upon the identity of the knowing with the willing Subject, as shown in § 42, that the influence is based, which the will exercises over the intellect, when it obliges it to repeat representations that have once been present to it, and in general to turn its attention in this

or that direction and evoke at pleasure any particular series of thoughts. And even in this, the will is determined by the law of motives, in accordance with which it also secretly rules what is called the association of ideas, to which I have devoted a separate chapter (the 14th) in the second volume of my chief work. This association of ideas is itself nothing but the application of the Principle of Sufficient Reason in its four forms to the subjective train of thought; that is, to the presence of representations in our consciousness. But it is the will of the individual that sets the whole mechanism in motion, by urging the intellect, in accordance with the interest, *i.e.*, the individual aims, of the person, to recall, together with its present representations, those which either logically or analogically, or by proximity in Time or Space, are nearly related to them. The will's activity in this, however, is so immediate, that in most cases we have no clear consciousness of it; and so rapid, that we are at times even unconscious of the occasion which has thus called forth a representation. In such cases, it appears as if something had come into our consciousness quite independently of all connection with anything else; that this, however, is impossible, is precisely the Root of the Principle of Sufficient Reason, which has been fully explained in the above-mentioned chapter of my chief work.[155] Every picture which suddenly presents itself to our imagination, every judgment even that does not follow its previously present reason, must be called forth by an act of volition having a motive; although that motive may often escape our perception owing to its insignificance, and although such acts of volition are often in like manner unperceived, because they take place so easily, that wish and fulfilment are simultaneous.

§ 45. *Memory.*

That peculiar faculty of the knowing Subject which enables it to obey the will the more readily in repeating representations, the oftener they have already been present to it — in other words, its capacity for being exercised — is what we call *Memory*. I cannot agree with the customary view, by which it is looked upon as a sort of store-house in which we keep a stock of ready-made representations always at our disposal, only without being always conscious of their possession. The voluntary repetition of representations which have once been present becomes so easy through practice, that one link in a series of representations no sooner becomes

present to us, than we at once evoke all the rest, often even, as it were, involuntarily. If we were to look for a metaphor for this characteristic quality of our representative faculty (such as that of Plato, who compared it with a soft mass that receives and retains impressions), I think the best would be that of a piece of drapery, which, after having been repeatedly folded in the same folds, at last falls into them, as it were, of its own accord. The body learns by practice to obey the will, and the faculty of representing does precisely the same. A remembrance is not by any means, as the usual view supposes, always the same representation which is, as it were, fetched over and over again from its store-house; a new one, on the contrary, arises each time, only practice makes this especially easy. Thus it comes to pass that pictures of our imagination, which we fancy we have stowed away in our memory, become imperceptibly modified: a thing which we realize when we see some familiar object again after a long time, and find that it no longer completely corresponds to the image we bring with us. This could not be if we retained ready-made representations. It is just for this reason too, that acquired knowledge, if left unexercised, gradually fades from our memory, precisely because it was the result of practice coming from habit and knack; thus most scholars, for instance, forget their Greek, and most artists their Italian on their return from Italy. This is also why we find so much difficulty in recalling to mind a name or a line of poetry formerly familiar to us, when we have ceased to think of it for several years; whereas when once we succeed in remembering it, we have it again at our disposal for some time, because the practice has been renewed. Everyone therefore who knows several languages, will do well to make a point of reading occasionally in each, that he may ensure to himself their possession.

This likewise explains why the surroundings and events of our childhood impress themselves so deeply on our memory; it is because, in childhood we have but few, and those chiefly intuitive, representations: so that we are induced to repeat them constantly for the sake of occupation. People who have little capability for original thought do this all their lives (and moreover not only with intuitive representations, but with conceptions and words also); sometimes therefore they have remarkably good memories, when obtuseness and sluggishness of intellect do not act as impediments. Men of genius, on the contrary, are not always endowed with the best of memories, as, for instance, Rousseau has told us of himself. Perhaps this may be accounted for by their great abundance of new thoughts and

combinations, which leaves them no time for frequent repetition. Still, on the whole, genius is seldom found with a very bad memory; because here a greater energy and mobility of the whole thinking faculty makes up for the want of constant practice. Nor must we forget that Mnemosyne was the mother of the Muses. We may accordingly say, that our memory stands under two contending influences, that of the energy of the representative faculty on the one hand, and that of the quantity of representations occupying that faculty on the other. The less energy there is in the faculty, the fewer must be the representations, and conversely. This explains the impaired memory of habitual novel-readers, for it is with them as with men of genius: the multitude of representations following rapidly upon each other, leaves no time or patience for repetition and practice; only, in novels, these representations are not the readers' own, but other people's thoughts and combinations quickly succeeding each other, and the readers themselves are wanting in that which, in genius, counterbalances repetition. The whole thing besides is subject to the corrective, that we all have most memory for that which interests us, and least for that which does not. Great minds therefore are apt to forget in an incredibly short time the petty affairs and trifling occurrences of daily life and the commonplace people with whom they come in contact, whereas they have a wonderful recollection of those things which have importance in themselves and for them.

It is, however, on the whole, easy to understand that we should more readily remember such series of representations as are connected together by the thread of one or more of the above-mentioned species of reasons and consequences, than such as have no connection with one another, but only with our will according to the law of motives; that is to say, those which are arbitrarily grouped. For, in the former, the fact that we know the formal part *à priori*, saves us half the trouble; and this probably gave rise to Plato's doctrine, that all learning is mere remembering.

As far as possible we ought to try and reduce all that we wish to incorporate in our memory to a perceptible image, either directly, or as an example, a mere simile, or an analogue, or indeed in any other way; because intuitive perceptions take a far firmer hold than any abstract thoughts, let alone mere words. This is why we remember things we have ourselves experienced so much better than those of which we read.

CHAPTER VIII. GENERAL OBSERVATIONS AND RESULTS.

§ 46. *The Systematic Order.*

The order of succession in which I have stated the various forms of the Principle of Sufficient Reason in this treatise, is not systematic; it has been chosen for the sake of greater clearness, in order first to present what is better known and least presupposes the rest. In this I have followed Aristotle's rule: καὶ μαθήσεως οὐκ ἀπὸ τοῦ πρώτου, καὶ τῆς τοῦ πράγματος ἀρχῆς ἐνίοτε ἀρκτέον, ἀλλ' ὅθεν ῥᾷστ' ἂν μάθοι (*et doctrina non a primo, ac rei principio aliquando inchoanda est, sed unde quis facilius discat*).[156] But the systematic order in which the different classes of reasons ought to follow one another is the following. First of all should come The Principle of Sufficient Reason of Being; and in this again first its application to Time, as being the simple schema containing only what is essential in all the other forms of the Principle of Sufficient Reason, nay, as being the prototype of all finitude. The Reason of Being in Space having next been stated, the Law of Causality would then follow; after which would come the Law of Motives, and last of all the Principle of Sufficient Reason of Knowing; for the other classes of reasons refer to immediate representations, whereas this last class refers to representations derived from other representations.

The truth expressed above, that Time is the simple schema which merely contains the essential part of all the forms of the Principle of Sufficient Reason, explains the absolutely perfect clearness and precision of Arithmetic, a point in which no other science can compete with it. For all sciences, being throughout combinations of reasons and consequences, are based upon the Principle of Sufficient Reason. Now, the series of numbers is the simple and only series of reasons and consequences of Being in Time; on account of this perfect simplicity — nothing being omitted, no indefinite relations left — this series leaves nothing to be desired as regards accuracy, apodeictic certainty and clearness. All the other sciences yield precedence in this respect to Arithmetic; even Geometry: because so many relations arise out of the three dimensions of Space, that a comprehensive synopsis of them becomes too difficult, not only for pure, but even for empirical intuition; complicated geometrical problems are therefore only solved by

calculation; that is, Geometry is quick to resolve itself into Arithmetic. It is not necessary to point out the existence of sundry elements of obscurity in the other sciences.

§ 47. *Relation in Time between Reason and Consequence.*

According to the laws of causality and of motivation, a reason must precede its consequence in Time. That this is absolutely essential, I have shown in my chief work, to which I here refer my readers[157] in order to avoid repeating myself. Therefore, if we only bear in mind that it is not one thing which is the cause of another thing, but one state which is the cause of another state, we shall not allow ourselves to be misled by examples like that given by Kant,[158] that the stove, which is the cause of the warmth of the room, is simultaneous with its effect. The state of the stove: that is, its being warmer than its surrounding medium, must precede the communication of its surplus caloric to that medium; now, as each layer of air on becoming warm makes way for a cooler layer rushing in, the first state, the cause, and consequently also the second, the effect, are renewed until at last the temperature of stove and room become equalized. Here therefore we have no permanent cause (the stove) and permanent effect (the warmth of the room) as simultaneous things, but a chain of changes; that is, a constant renewing of two states, one of which is the effect of the other. From this example, however, it is obvious that even Kant's conception of Causality was far from clear.

On the other hand, the Principle of Sufficient Reason of Knowing conveys with it no relation in Time, but merely a relation for our Reason: here therefore, *before* and *after* have no meaning.

In the Principle of Sufficient Reason of Being, so far as it is valid in Geometry, there is likewise no relation in Time, but only a relation in Space, of which we might say that all things were co-existent, if here the words co-existence and succession had any meaning. In Arithmetic, on the contrary, the Reason of Being is nothing else but precisely the relation of Time itself.

§ 48. *Reciprocity of Reasons.*

Hypothetical judgments may be founded upon the Principle of Sufficient Reason in each of its significations, as indeed every hypothetical judgment

is ultimately based upon that principle, and here the laws of hypothetical conclusions always hold good: that is to say, it is right to infer the existence of the consequence from the existence of the reason, and the non-existence of the reason from the non-existence of the consequence; but it is wrong to infer the non-existence of the consequence from the non-existence of the reason, and the existence of the reason from the existence of the consequence. Now it is singular that in Geometry we are nevertheless nearly always able to infer the existence of the reason from the existence of the consequence, and the non-existence of the consequence from the non-existence of the reason. This proceeds, as I have shown in § 37, from the fact that, as each line determines the position of the rest, it is quite indifferent which we begin at: that is, which we consider as the reason, and which as the consequence. We may easily convince ourselves of this by going through the whole of the geometrical theorems. It is only where we have to do not only with figures, *i.e.*, with the positions of lines, but with planes independently of figures, that we find it in most cases impossible to infer the existence of the reason from the existence of the consequence, or, in other words, to convert the propositions by making the condition the conditioned. The following theorem gives an instance of this: Triangles whose lengths and bases are equal, include equal areas. This cannot be converted as follows: Triangles whose areas are equal, have likewise equal bases and lengths; for the lengths may stand in inverse proportion to the bases.

In § 20 it has already been shown, that the law of causality does not admit of reciprocity, since the effect never can be the cause of its cause; therefore the conception of reciprocity is, in its right sense, inadmissible. Reciprocity, according to the Principle of Sufficient Reason of knowing, would only be possible between equivalent conceptions, since the spheres of these alone cover each other mutually. Apart from these, it only gives rise to a vicious circle.

§ 49. *Necessity.*

The Principle of Sufficient Reason in all its forms is the sole principle and the sole support of all necessity. For *necessity* has no other true and distinct meaning than that of the infallibility of the consequence when the reason is posited. Accordingly every necessity is *conditioned*: absolute, *i.e.*,

unconditioned, necessity therefore is a *contradicto in adjecto*. For *to be necessary* can never mean anything but to result from a given reason. By defining it as "what cannot not be," on the other hand, we give a mere verbal definition, and screen ourselves behind an extremely abstract conception to avoid giving a definition of the thing. But it is not difficult to drive us from this refuge by inquiring how the non-existence of anything can be possible or even conceivable, since all existence is only given empirically. It then comes out, that it is only possible so far as some *reason* or other is posited or present, from which it follows. To be necessary and to follow from a given reason, are thus convertible conceptions, and may always, as such, be substituted one for the other. The conception of an "ABSOLUTELY *necessary Being*" which finds so much favour with pseudo-philosophers, contains therefore a contradiction: it annuls by the predicate "*absolute*" (*i.e.*, "unconditioned by anything else") the only determination which makes the "*necessary*" conceivable. Here again we have an instance of the *improper use of abstract conceptions* to play off a metaphysical artifice such as those I have already pointed out in the conceptions "*immaterial substance*," "*cause in general*," "*absolute reason*," &c. &c.[159] I can never insist too much upon all abstract conceptions being checked by *perception*.

There exists accordingly a *fourfold* necessity, in conformity with the *four* forms of the Principle of Sufficient Reason: —

1°. *Logical necessity*, according to the principle of sufficient reason of knowing, in virtue of which, when once we have admitted the premisses, we must absolutely admit the conclusion.

2°. *Physical necessity*, according to the law of causality, in virtue of which, as soon as the cause presents itself, the effect must infallibly follow.

3°. *Mathematical necessity*, according to the principle of sufficient reason of being, in virtue of which, every relation which is stated in a true geometrical theorem, is as that theorem affirms it to be, and every correct calculation remains irrefutable.

4°. *Moral necessity*, in virtue of which, every human being, every animal even, is *compelled*, as soon as a motive presents itself, to do that which alone is in accordance with the inborn and immutable character of the individual. This action now follows its cause therefore as infallibly as every other effect, though it is less easy here to predict what that effect will be

than in other cases, because of the difficulty we have in fathoming and completely knowing the individual empirical character and its allotted sphere of knowledge, which is indeed a very different thing from ascertaining the chemical properties of a neutral salt and predicting its reaction. I must repeat this again and again on account of the dunces and blockheads who, in defiance of the unanimous authority of so many great thinkers, still persist in audaciously maintaining the contrary, for the benefit of their old woman's philosophy. I am not a professor of philosophy, forsooth, that I need bow to the folly of others.

§ 50. *Series of Reasons and Consequences.*

According to the law of causality, the condition is itself always conditioned, and, moreover, conditioned in the same way; therefore, there arises a series *in infinitum a parte ante*. It is just the same with the Reason of Being in Space: each relative space is a figure; it has its limits, by which it is connected with another relative space, and which themselves condition the figure of this other, and so on throughout all dimensions *in infinitum*. But when we examine a single figure in itself, the series of reasons of being has an end, because we start from a given relation, just as the series of causes comes to an end if we stop at pleasure at any particular cause. In Time, the series of reasons of being has infinite extension both *a parte ante*, and *a parte post*, since each moment is conditioned by a preceding one, and necessarily gives rise to the following. Time has therefore neither beginning nor end. On the other hand, the series of reasons of knowledge — that is, a series of judgments, each of which gives logical truth to the other — always ends somewhere, *i.e.*, either in an empirical, a transcendental, or a metalogical truth. If the reason of the major to which we have been led is an empirical truth, and we still continue asking *why*, it is no longer a reason of knowledge that is asked for, but a cause — in other words, the series of reasons of knowing passes over into the series of reasons of becoming. But if we do the contrary, that is, if we allow the series of reasons of becoming to pass over into the series of reasons of knowing, in order to bring it to an end, this is never brought about by the nature of the thing, but always by a special purpose: it is therefore a trick, and this is the sophism known by the name of the Ontological Proof. For when a cause, at which it seems desirable to stop short in order to make it the *first* cause, has been reached

by means of the Cosmological Proof, we find out that the law of causality is not so easily brought to a standstill, and still persists in asking *why*: so it is simply set aside and the principle of sufficient reason of knowing, which from a distance resembles it, is substituted in its stead; and thus a reason of knowledge is given in the place of the cause which had been asked for — a reason of knowledge derived from the conception itself which has to be demonstrated, the reality of which is therefore still problematical: and this reason, as after all it is one, now has to figure as a cause. Of course the conception itself has been previously arranged for this purpose, and reality slightly covered with a few husks just for decency's sake has been placed within it, so as to give the delightful surprise of finding it there — as has been shown in Section 7. On the other hand, if a chain of judgments ultimately rests upon a principle of transcendental or of metalogical truth, and we still continue to ask *why*, we receive no answer at all, because the question has no meaning, *i.e.*, it does not know what kind of reason it is asking for.

For the Principle of Sufficient Reason is the *principle of all explanation: to explain a thing* means, to reduce its given existence or connection to some form or other of the Principle of Sufficient Reason, in accordance with which form that existence or connection necessarily is that which it is. The Principle of Sufficient Reason itself, *i.e.*, the connection expressed by it in any of its forms, cannot therefore be further explained; because there exists no principle by which to explain the source of all explanation: just as the eye is unable to see itself, though it sees everything else. There are of course series of motives, since the resolve to attain an end becomes the motive for the resolve to use a whole series of means; still this series invariably ends *à parte priori* in a representation belonging to one of our two first classes, in which lies the motive which originally had the power to set this individual will in motion. The fact that it was able to do this, is a datum for knowing the empirical character here given, but it is impossible to answer the question why that particular motive acts upon that particular character; because the intelligible character lies outside Time and never becomes an Object. Therefore the series of motives, as such, finds its termination in some such final motive and, according to the nature of its last link, passes into the series of causes, or that of reasons of knowledge: that is to say, into the former, when that last link is a real object; into the latter, when it is a mere conception.

§ 51. *Each Science has for its Guiding Thread one of the Forms of the Principle of Sufficient Reason in preference to the others.*

As the question *why* always demands a sufficient reason, and as it is the connection of its notions according to the principle of sufficient reason which distinguishes science from a mere aggregate of notions, we have called that *why* the parent of all science (§ 4). In each science, moreover, we find one of the forms of that principle predominating over the others as its guiding-thread. Thus in pure Mathematics the reason of being is the chief guiding-thread (although the exposition of the proofs proceeds according to the reason of knowing only); in applied Mathematics the law of causality appears together with it, but in Physics, Chemistry, Geology, &c., that law entirely predominates. The principle of sufficient reason in knowing finds vigorous application throughout all the sciences, for in all of them the particular is known through the general; but in Botany, Zoology, Mineralogy, and other classifying sciences, it is the chief guide and predominates absolutely. The law of motives (*motivation*) is the chief guide in History, Politics, Pragmatic Psychology, &c. &c., when we consider all motives and maxims, whatever they may be, as data for explaining actions — but when we make those motives and maxims the object-matter of investigation from the point of view of their value and origin, the law of motives becomes the guide to Ethics. In my chief work will be found the highest classification of the sciences according to this principle.[160]

§ 52. *Two principal Results.*

I have endeavoured in this treatise to show that the Principle of Sufficient Reason is a common expression for four completely different relations, each of which is founded upon a particular law given *à priori* (the principle of sufficient reason being a synthetical *à priori* principle). Now, according to the principle of *homogeneity*, we are compelled to assume that these four laws, discovered according to the principle of specification, as they agree in being expressed by one and the same term, must necessarily spring from one and the same original quality of our whole cognitive faculty as their common root, which we should accordingly have to look upon as the innermost germ of all dependence, relativeness, instability and limitation of the objects of our consciousness — itself limited to Sensibility,

Understanding, Reason, Subject and Object — or of that world, which the divine Plato repeatedly degrades to the ἀεὶ γιγνόμενον μὲν καὶ ἀπολλύμενον, ὄντως δὲ οὐδέποτε ὄν (ever arising and perishing, but in fact never existing), the knowledge of which is merely a δόξα μετ’ αἰσθήσεως ἀλόγου, and which Christendom, with a correct instinct, calls *temporal*, after that form of our principle (Time) which I have defined as its simplest schema and the prototype of all limitation. The general meaning of the Principle of Sufficient Reason may, in the main, be brought back to this: that every thing existing no matter when or where, exists *by reason of something else*. Now, the Principle of Sufficient Reason is nevertheless *à priori* in all its forms: that is, it has its root in our intellect, therefore it must not be applied to the totality of existent things, the Universe, including that intellect in which it presents itself. For a world like this, which presents itself in virtue of *à priori* forms, is just on that account mere phenomenon; consequently that which holds good with reference to it as the result of these forms, cannot be applied to the world itself, *i.e.* to the thing in itself, representing itself in that world. Therefore we cannot say, “the world and all things in it exist by reason of something else;” and this proposition is precisely the Cosmological Proof.

If, by the present treatise, I have succeeded in deducing the result just expressed, it seems to me that every speculative philosopher who founds a conclusion upon the Principle of Sufficient Reason or indeed talks of a reason at all, is bound to specify which kind of reason he means. One might suppose that wherever there was any question of a reason, this would be done as a matter of course, and that all confusion would thus be impossible. Only too often, however, do we still find either the terms reason and cause confounded in indiscriminate use; or do we hear basis and what is based, condition and what is conditioned, *principia* and *principiata* talked about in quite a *general* way without any nearer determination, perhaps because there is a secret consciousness that these conceptions are being used in an unauthorized way. Thus even Kant speaks of the thing in itself as the *reason*[161] of the phenomenon, and also of a *ground* of the *possibility* of all phenomena,[162] of an *intelligible cause* of phenomena, of an *unknown ground* of the possibility of the sensuous series in general, of a *transcendental object*[163] as the *ground* of all phenomena and of the *reason* why our sensibility should have this rather than all other supreme conditions, and so

on in several places. Now all this does not seem to me to tally with those weighty, profound, nay immortal words of his,[164] "the contingency[165] of things is itself mere phenomenon, and can lead to no other than the empirical regressus which determines phenomena."

That since Kant the conceptions reason and consequence, *principium* and *principiatum*, &c. &c., have been and still are used in a yet more indefinite and even quite transcendent sense, everyone must know who is acquainted with the more recent works on philosophy.

The following is my objection against this promiscuous employment of the word *ground* (reason) and, with it, of the Principle of Sufficient Reason in general; it is likewise the second result, intimately connected with the first, which the present treatise gives concerning its subject-matter proper. The four laws of our cognitive faculty, of which the Principle of Sufficient Reason is the common expression, by their common character as well as by the fact that all Objects for the Subject are divided amongst them, proclaim themselves to be posited by one and the same primary quality and inner peculiarity of our knowing faculty, which faculty manifests itself as Sensibility, Understanding, and Reason. Therefore, even if we imagined it to be possible for a new Fifth Class of Objects to come about, we should in that case likewise have to assume that the Principle of Sufficient Reason would appear in this class also under a different form. Notwithstanding all this, we still have no right to talk of an *absolute reason* (ground), nor does a *reason in general*, any more than a *triangle in general*, exist otherwise than as a conception derived by means of discursive reflection, nor is this conception, as a representation drawn from other representations, anything more than a means of thinking several things in one. Now, just as every triangle must be either acute-angled, right-angled, or obtuse-angled, and either equilateral, isosceles or scalene, so also must every reason belong to one or other of the four possible kinds of reasons I have pointed out. Moreover, since we have only four well-distinguished Classes of Objects, every reason must also belong to one or other of these four, and no further Class being possible, Reason itself is forced to rank it within them; for as soon as we employ a reason, we presuppose the Four Classes as well as the faculty of representing (*i.e.* the whole world), and must hold ourselves within these bounds, never transcending them. Should others, however, see this in a different light and opine that a *reason in general* is anything but a conception, derived from the four kinds of reasons, which expresses what

they all have in common, we might revive the controversy of the Realists and Nominalists, and then I should side with the latter.

ENDNOTES.

80 The Frankfort "Konversationsblatt," July 22, 1853, gives the following account of this sculptor:— "The blind sculptor, Joseph Kleinhaus, died at Nauders, in Tyrol, on the 10th inst. Having lost his

eyesight through small-pox when he was five years old, he began to amuse himself with carving and modelling, as a pastime. Prugg gave him some instructions, and supplied him with models, and at the age of twelve he carved a Christ in life-size. During a short stay in Nissl's workshop at Fügen, his progress was so rapid, that, thanks to his good capacities and talents, his fame as the blind sculptor soon spread far and wide. His works are numerous and of various kinds. His Christs alone, of which there are about four hundred, bear special witness to his proficiency, particularly if his blindness is taken into consideration. He sculptured many other objects besides, and, but two months ago, he modelled a bust of the Emperor Franz Joseph of Austria which has been sent to Vienna."

[160] "Die Welt a. W. u. V.," vol. ii. ch. 12, p. 126 of the 2nd edition (p. 139 of the 3rd edition).

[161] Or *ground*.

[162] Kant, "Krit. d. r. Vern.," 1st edition, pp. 561, 562, 564; p. 590 of the 5th edition. (Pp. 483 to 486 of the English translation by M. Müller.)

[163] *Ibid.* p. 540 of 1st edition, and 641 of 5th edition. (P. 466 of English translation.)

[164] *Ibid.* p. 563 of the 1st and 591 of the 5th edition. (P. 485 of English translation.)

[165] Empirical contingency is meant, which, with Kant, signifies as much as dependence upon other things. As to this, I refer my readers to my censure in my "Critique of Kantian Philosophy," p. 524 of the 2nd, and p. 552 of the 3rd edition.

THE WORLD AS WILL AND IDEA

Translated by R. B. Haldane and J. Kemp

THE SIXTH EDITION, 1909

Widely considered Schopenhauer's most important work, *The World as Will and Idea* was first published in 1818, with an expanded edition appearing in 1844 and a third expanded edition in 1859. The fundamental idea of this text, which is condensed into a short formula in the title itself, is developed in four books composed of two comprehensive series of reflections that include successively the theory of knowledge and the philosophy of nature, aesthetics and ethics.

The first book opens with a reference to Kant and Schopenhauer argues again that 'the world is my representation'. He proposes that this is only comprehensible with the aid of the constructs of man's intellect — namely space, time and causality. But these constructs reveal the world only as appearance, as a multiplicity of things next to and following one another — not as the thing in itself that Kant considered to be unknowable. The second book progresses to a consideration of the essences of the concepts presented. Of all the things in the world, only one is presented to a person in two ways: he knows himself externally as body or as appearance, and he knows himself internally as part of the primary essence of all things, as will. The will is the thing in itself. It is unitary, unfathomable, unchangeable, beyond space and time, without causes and purposes. In the world of appearances, it is reflected in an ascending series of realisations. From the blind impulses in the forces of inorganic nature, through organic to the rationally guided actions of men, a great chain of restless desires, agitations and drives stretch forth — a continual struggle of the higher forms against the lower, an eternally aimless and insatiable striving, inseparably united with misery and misfortune. At the end, however, stands death, the great reproof that the will-to-live receives, posing the question to each single person: 'Have you had enough?'

The development of Schopenhauer's ideas took place early in his career and culminated with the publication of the first volume of *World as Will and*

Idea in 1819. This first volume consisted of four books – covering his epistemology, ontology, aesthetics and ethics, in order. Much later in his life, in 1844, Schopenhauer published a second edition in two volumes, the first a virtual reprint of the original, and the second a new work consisting of clarifications to and additional reflections on the first. His views had not changed substantially. His belated fame after 1851 stimulated renewed interest in his seminal work, leading to a third and final edition with 136 more pages in 1859, one year before his death. In the preface to the latter, Schopenhauer noted: "If I also have at last arrived, and have the satisfaction at the end of my life of seeing the beginning of my influence, it is with the hope that, according to an old rule, it will last longer in proportion to the lateness of its beginning."

Die Welt

als

Wille und Vorstellung.

Von

Arthur Schopenhauer.

Zweite, durchgängig verbesserte und sehr vermehrte Auflage.

Erster Band,

Vier Bücher, nebst einem Anhange, der die Kritik der Kantischen Philosophie enthält.

Ob nicht Natur zuletzt sich doch ergründe?
Göthe.

Leipzig:
F. A. Brockhaus.

VOLUME III.

Schopenhauer in 1815

VOLUME I.

Translators' Preface.

The style of "Die Welt als Wille und Vorstellung" is sometimes loose and involved, as is so often the case in German philosophical treatises. The translation of the book has consequently been a matter of no little difficulty. It was found that extensive alteration of the long and occasionally involved sentences, however likely to prove conducive to a satisfactory English style, tended not only to obliterate the form of the original but even to imperil the meaning. Where a choice has had to be made, the alternative of a somewhat slavish adherence to Schopenhauer's *ipsissima verba* has accordingly been preferred to that of inaccuracy. The result is a piece of work which leaves much to be desired, but which has yet consistently sought to reproduce faithfully the spirit as well as the letter of the original.

As regards the rendering of the technical terms about which there has been so much controversy, the equivalents used have only been adopted after careful consideration of their meaning in the theory of knowledge. For example, "Vorstellung" has been rendered by "idea," in preference to "representation," which is neither accurate, intelligible, nor elegant. "Idee," is translated by the same word, but spelled with a capital,— "Idea." Again, "Anschauung" has been rendered according to the context, either by "perception" simply, or by "intuition or perception."

Notwithstanding statements to the contrary in the text, the book is probably quite intelligible in itself, apart from the treatise "On the Fourfold Root of the Principle of Sufficient Reason." It has, however, been considered desirable to add an abstract of the latter work in an appendix to the third volume of this translation.

J. K.

Preface To The First Edition.

I propose to point out here how this book must be read in order to be thoroughly understood. By means of it I only intend to impart a single thought. Yet, notwithstanding all my endeavours, I could find no shorter way of imparting it than this whole book. I hold this thought to be that which has very long been sought for under the name of philosophy, and the discovery of which is therefore regarded by those who are familiar with history as quite as impossible as the discovery of the philosopher's stone, although it was already said by Pliny: *Quam multa fieri non posse, priusquam sint facta, judicantur?* (Hist. nat. 7, 1.)

According as we consider the different aspects of this one thought which I am about to impart, it exhibits itself as that which we call metaphysics, that which we call ethics, and that which we call æsthetics; and certainly it must be all this if it is what I have already acknowledged I take it to be.

A *system of thought* must always have an architectonic connection or coherence, that is, a connection in which one part always supports the other, though the latter does not support the former, in which ultimately the foundation supports all the rest without being supported by it, and the apex is supported without supporting. On the other hand, a *single thought*, however comprehensive it may be, must preserve the most perfect unity. If it admits of being broken up into parts to facilitate its communication, the connection of these parts must yet be organic, *i.e.*, it must be a connection in which every part supports the whole just as much as it is supported by it, a connection in which there is no first and no last, in which the whole thought gains distinctness through every part, and even the smallest part cannot be completely understood unless the whole has already been grasped. A book, however, must always have a first and a last line, and in this respect will always remain very unlike an organism, however like one its content may be: thus form and matter are here in contradiction.

It is self-evident that under these circumstances no other advice can be given as to how one may enter into the thought explained in this work than *to read the book twice*, and the first time with great patience, a patience which is only to be derived from the belief, voluntarily accorded, that the beginning presupposes the end almost as much as the end presupposes the beginning, and that all the earlier parts presuppose the later almost as much

as the later presuppose the earlier. I say "almost;" for this is by no means absolutely the case, and I have honestly and conscientiously done all that was possible to give priority to that which stands least in need of explanation from what follows, as indeed generally to everything that can help to make the thought as easy to comprehend and as distinct as possible. This might indeed to a certain extent be achieved if it were not that the reader, as is very natural, thinks, as he reads, not merely of what is actually said, but also of its possible consequences, and thus besides the many contradictions actually given of the opinions of the time, and presumably of the reader, there may be added as many more which are anticipated and imaginary. That, then, which is really only misunderstanding, must take the form of active disapproval, and it is all the more difficult to recognise that it is misunderstanding, because although the laboriously-attained clearness of the explanation and distinctness of the expression never leaves the immediate sense of what is said doubtful, it cannot at the same time express its relations to all that remains to be said. Therefore, as we have said, the first perusal demands patience, founded on confidence that on a second perusal much, or all, will appear in an entirely different light. Further, the earnest endeavour to be more completely and even more easily comprehended in the case of a very difficult subject, must justify occasional repetition. Indeed the structure of the whole, which is organic, not a mere chain, makes it necessary sometimes to touch on the same point twice. Moreover this construction, and the very close connection of all the parts, has not left open to me the division into chapters and paragraphs which I should otherwise have regarded as very important, but has obliged me to rest satisfied with four principal divisions, as it were four aspects of one thought. In each of these four books it is especially important to guard against losing sight, in the details which must necessarily be discussed, of the principal thought to which they belong, and the progress of the whole exposition. I have thus expressed the first, and like those which follow, unavoidable demand upon the reader, who holds the philosopher in small favour just because he himself is a philosopher.

The second demand is this, that the introduction be read before the book itself, although it is not contained in the book, but appeared five years earlier under the title, "*Ueber die vierfache Wurzel des Satzes vom zureichenden Grunde: eine philosophische Abhandlung*" (On the fourfold root of the principle of sufficient reason: a philosophical essay). Without an

acquaintance with this introduction and propadeutic it is absolutely impossible to understand the present work properly, and the content of that essay will always be presupposed in this work just as if it were given with it. Besides, even if it had not preceded this book by several years, it would not properly have been placed before it as an introduction, but would have been incorporated in the first book. As it is, the first book does not contain what was said in the earlier essay, and it therefore exhibits a certain incompleteness on account of these deficiencies, which must always be supplied by reference to it. However, my disinclination was so great either to quote myself or laboriously to state again in other words what I had already said once in an adequate manner, that I preferred this course, notwithstanding the fact that I might now be able to give the content of that essay a somewhat better expression, chiefly by freeing it from several conceptions which resulted from the excessive influence which the Kantian philosophy had over me at the time, such as — categories, outer and inner sense, and the like. But even there these conceptions only occur because as yet I had never really entered deeply into them, therefore only by the way and quite out of connection with the principal matter. The correction of such passages in that essay will consequently take place of its own accord in the mind of the reader through his acquaintance with the present work. But only if we have fully recognised by means of that essay what the principle of sufficient reason is and signifies, what its validity extends to, and what it does not extend to, and that that principle is not before all things, and the whole world merely in consequence of it, and in conformity to it, a corollary, as it were, of it; but rather that it is merely the form in which the object, of whatever kind it may be, which is always conditioned by the subject, is invariably known so far as the subject is a knowing individual: only then will it be possible to enter into the method of philosophy which is here attempted for the first time, and which is completely different from all previous methods.

But the same disinclination to repeat myself word for word, or to say the same thing a second time in other and worse words, after I have deprived myself of the better, has occasioned another defect in the first book of this work. For I have omitted all that is said in the first chapter of my essay “On Sight and Colour,” which would otherwise have found its place here, word for word. Therefore the knowledge of this short, earlier work is also presupposed.

Finally, the third demand I have to make on the reader might indeed be tacitly assumed, for it is nothing but an acquaintance with the most important phenomenon that has appeared in philosophy for two thousand years, and that lies so near us: I mean the principal writings of Kant. It seems to me, in fact, as indeed has already been said by others, that the effect these writings produce in the mind to which they truly speak is very like that of the operation for cataract on a blind man: and if we wish to pursue the simile further, the aim of my own work may be described by saying that I have sought to put into the hands of those upon whom that operation has been successfully performed a pair of spectacles suitable to eyes that have recovered their sight — spectacles of whose use that operation is the absolutely necessary condition. Starting then, as I do to a large extent, from what has been accomplished by the great Kant, I have yet been enabled, just on account of my earnest study of his writings, to discover important errors in them. These I have been obliged to separate from the rest and prove to be false, in order that I might be able to presuppose and apply what is true and excellent in his doctrine, pure and freed from error. But not to interrupt and complicate my own exposition by a constant polemic against Kant, I have relegated this to a special appendix. It follows then, from what has been said, that my work presupposes a knowledge of this appendix just as much as it presupposes a knowledge of the philosophy of Kant; and in this respect it would therefore be advisable to read the appendix first, all the more as its content is specially related to the first book of the present work. On the other hand, it could not be avoided, from the nature of the case, that here and there the appendix also should refer to the text of the work; and the only result of this is, that the appendix, as well as the principal part of the work, must be read twice.

The philosophy of Kant, then, is the only philosophy with which a thorough acquaintance is directly presupposed in what we have to say here. But if, besides this, the reader has lingered in the school of the divine Plato, he will be so much the better prepared to hear me, and susceptible to what I say. And if, indeed, in addition to this he is a partaker of the benefit conferred by the Vedas, the access to which, opened to us through the Upanishads, is in my eyes the greatest advantage which this still young century enjoys over previous ones, because I believe that the influence of the Sanscrit literature will penetrate not less deeply than did the revival of Greek literature in the fifteenth century: if, I say, the reader has also already

received and assimilated the sacred, primitive Indian wisdom, then is he best of all prepared to hear what I have to say to him. My work will not speak to him, as to many others, in a strange and even hostile tongue; for, if it does not sound too vain, I might express the opinion that each one of the individual and disconnected aphorisms which make up the Upanishads may be deduced as a consequence from the thought I am going to impart, though the converse, that my thought is to be found in the Upanishads, is by no means the case.

But most readers have already grown angry with impatience, and burst into reproaches with difficulty kept back so long. How can I venture to present a book to the public under conditions and demands the first two of which are presumptuous and altogether immodest, and this at a time when there is such a general wealth of special ideas, that in Germany alone they are made common property through the press, in three thousand valuable, original, and absolutely indispensable works every year, besides innumerable periodicals, and even daily papers; at a time when especially there is not the least deficiency of entirely original and profound philosophers, but in Germany alone there are more of them alive at the same time, than several centuries could formerly boast of in succession to each other? How is one ever to come to the end, asks the indignant reader, if one must set to work upon a book in such a fashion?

As I have absolutely nothing to advance against these reproaches, I only hope for some small thanks from such readers for having warned them in time, so that they may not lose an hour over a book which it would be useless to read without complying with the demands that have been made, and which should therefore be left alone, particularly as apart from this we might wager a great deal that it can say nothing to them, but rather that it will always be only *pancorum hominum*, and must therefore quietly and modestly wait for the few whose unusual mode of thought may find it enjoyable. For apart from the difficulties and the effort which it requires from the reader, what cultured man of this age, whose knowledge has almost reached the august point at which the paradoxical and the false are all one to it, could bear to meet thoughts almost on every page that directly contradict that which he has yet himself established once for all as true and undeniable? And then, how disagreeably disappointed will many a one be if he finds no mention here of what he believes it is precisely here he ought to

look for, because his method of speculation agrees with that of a great living philosopher,[1] who has certainly written pathetic books, and who only has the trifling weakness that he takes all he learned and approved before his fifteenth year for inborn ideas of the human mind. Who could stand all this? Therefore my advice is simply to lay down the book.

But I fear I shall not escape even thus. The reader who has got as far as the preface and been stopped by it, has bought the book for cash, and asks how he is to be indemnified. My last refuge is now to remind him that he knows how to make use of a book in several ways, without exactly reading it. It may fill a gap in his library as well as many another, where, neatly bound, it will certainly look well. Or he can lay it on the toilet-table or the tea-table of some learned lady friend. Or, finally, what certainly is best of all, and I specially advise it, he can review it.

And now that I have allowed myself the jest to which in this two-sided life hardly any page can be too serious to grant a place, I part with the book with deep seriousness, in the sure hope that sooner or later it will reach those to whom alone it can be addressed; and for the rest, patiently resigned that the same fate should, in full measure, befall it, that in all ages has, to some extent, befallen all knowledge, and especially the weightiest knowledge of the truth, to which only a brief triumph is allotted between the two long periods in which it is condemned as paradoxical or disparaged as trivial. The former fate is also wont to befall its author. But life is short, and truth works far and lives long: let us speak the truth.

Written at Dresden in August 1818.

Preface To The Second Edition.

Not to my contemporaries, not to my compatriots — to mankind I commit my now completed work in the confidence that it will not be without value for them, even if this should be late recognised, as is commonly the lot of what is good. For it cannot have been for the passing generation, engrossed with the delusion of the moment, that my mind, almost against my will, has uninterruptedly stuck to its work through the course of a long life. And while the lapse of time has not been able to make me doubt the worth of my work, neither has the lack of sympathy; for I constantly saw the false and the bad, and finally the absurd and senseless,[2] stand in universal admiration and honour, and I bethought myself that if it were not the case those who are capable of recognising the genuine and right are so rare that we may look for them in vain for some twenty years, then those who are capable of producing it could not be so few that their works afterwards form an exception to the perishableness of earthly things; and thus would be lost the reviving prospect of posterity which every one who sets before himself a high aim requires to strengthen him.

Whoever seriously takes up and pursues an object that does not lead to material advantages, must not count on the sympathy of his contemporaries. For the most part he will see, however, that in the meantime the superficial aspect of that object becomes current in the world, and enjoys its day; and this is as it should be. The object itself must be pursued for its own sake, otherwise it cannot be attained; for any design or intention is always dangerous to insight. Accordingly, as the whole history of literature proves, everything of real value required a long time to gain acceptance, especially if it belonged to the class of instructive, not entertaining, works; and meanwhile the false flourished. For to combine the object with its superficial appearance is difficult, when it is not impossible. Indeed that is just the curse of this world of want and need, that everything must serve and slave for these; and therefore it is not so constituted that any noble and sublime effort, like the endeavour after light and truth, can prosper unhindered and exist for its own sake. But even if such an endeavour has once succeeded in asserting itself, and the conception of it has thus been introduced, material interests and personal aims will immediately take possession of it, in order to make it their tool or their

mask. Accordingly, when Kant brought philosophy again into repute, it had soon to become the tool of political aims from above, and personal aims from below; although, strictly speaking, not philosophy itself, but its ghost, that passes for it. This should not really astonish us; for the incredibly large majority of men are by nature quite incapable of any but material aims, indeed they can conceive no others. Thus the pursuit of truth alone is far too lofty and eccentric an endeavour for us to expect all or many, or indeed even a few, faithfully to take part in. If yet we see, as for example at present in Germany, a remarkable activity, a general moving, writing, and talking with reference to philosophical subjects, we may confidently assume that, in spite of solemn looks and assurances, only real, not ideal aims, are the actual *primum mobile*, the concealed motive of such a movement; that it is personal, official, ecclesiastical, political, in short, material ends that are really kept in view, and consequently that mere party ends set the pens of so many pretended philosophers in such rapid motion. Thus some design or intention, not the desire of insight, is the guiding star of these disturbers of the peace, and truth is certainly the last thing that is thought of in the matter. It finds no partisans; rather, it may pursue its way as silently and unheeded through such a philosophical riot as through the winter night of the darkest century bound in the rigid faith of the church, when it was communicated only to a few alchemists as esoteric learning, or entrusted it may be only to the parchment. Indeed I might say that no time can be more unfavourable to philosophy than that in which it is shamefully misused, on the one hand to further political objects, on the other as a means of livelihood. Or is it believed that somehow, with such effort and such a turmoil, the truth, at which it by no means aims, will also be brought to light? Truth is no prostitute, that throws herself away upon those who do not desire her; she is rather so coy a beauty that he who sacrifices everything to her cannot even then be sure of her favour.

If Governments make philosophy a means of furthering political ends, learned men see in philosophical professorships a trade that nourishes the outer man just like any other; therefore they crowd after them in the assurance of their good intentions, that is, the purpose of subserving these ends. And they keep their word: not truth, not clearness, not Plato, not Aristotle, but the ends they were appointed to serve are their guiding star, and become at once the criterion of what is true, valuable, and to be respected, and of the opposites of these. Whatever, therefore, does not

answer these ends, even if it were the most important and extraordinary things in their department, is either condemned, or, when this seems hazardous, suppressed by being unanimously ignored. Look only at their zeal against pantheism; will any simpleton believe that it proceeds from conviction? And, in general, how is it possible that philosophy, degraded to the position of a means of making one's bread, can fail to degenerate into sophistry? Just because this is infallibly the case, and the rule, "I sing the song of him whose bread I eat," has always held good, the making of money by philosophy was regarded by the ancients as the characteristic of the sophists. But we have still to add this, that since throughout this world nothing is to be expected, can be demanded, or is to be had for gold but mediocrity, we must be contented with it here also. Consequently we see in all the German universities the cherished mediocrity striving to produce the philosophy which as yet is not there to produce, at its own expense and indeed in accordance with a predetermined standard and aim, a spectacle at which it would be almost cruel to mock.

While thus philosophy has long been obliged to serve entirely as a means to public ends on the one side and private ends on the other, I have pursued the course of my thought, undisturbed by them, for more than thirty years, and simply because I was obliged to do so and could not help myself, from an instinctive impulse, which was, however, supported by the confidence that anything true one may have thought, and anything obscure one may have thrown light upon, will appeal to any thinking mind, no matter when it comprehends it, and will rejoice and comfort it. To such an one we speak as those who are like us have spoken to us, and have so become our comfort in the wilderness of this life. Meanwhile the object is pursued on its own account and for its own sake. Now it happens curiously enough with philosophical meditations, that precisely that which one has thought out and investigated for oneself, is afterwards of benefit to others; not that, however, which was originally intended for others. The former is confessedly nearest in character to perfect honesty; for a man does not seek to deceive himself, nor does he offer himself empty husks; so that all sophistication and all mere talk is omitted, and consequently every sentence that is written at once repays the trouble of reading it. Thus my writings bear the stamp of honesty and openness so distinctly on the face of them, that by this alone they are a glaring contrast to those of three celebrated sophists of the post-Kantian period. I am always to be found at the

standpoint of *reflection*, *i.e.*, rational deliberation and honest statement, never at that of *inspiration*, called intellectual intuition, or absolute thought; though, if it received its proper name, it would be called empty bombast and charlatanism. Working then in this spirit, and always seeing the false and bad in universal acceptance, yea, bombast[3] and charlatanism[4] in the highest honour, I have long renounced the approbation of my contemporaries. It is impossible that an age which for twenty years has applauded a Hegel, that intellectual Caliban, as the greatest of the philosophers, so loudly that it echoes through the whole of Europe, could make him who has looked on at that desirous of its approbation. It has no more crowns of honour to bestow; its applause is prostituted, and its censure has no significance. That I mean what I say is attested by the fact that if I had in any way sought the approbation of my contemporaries, I would have had to strike out a score of passages which entirely contradict all their opinions, and indeed must in part be offensive to them. But I would count it a crime to sacrifice a single syllable to that approbation. My guiding star has, in all seriousness, been truth. Following it, I could first aspire only to my own approbation, entirely averted from an age deeply degraded as regards all higher intellectual efforts, and a national literature demoralised even to the exceptions, a literature in which the art of combining lofty words with paltry significance has reached its height. I can certainly never escape from the errors and weaknesses which, in my case as in every one else's, necessarily belong to my nature; but I will not increase them by unworthy accommodations.

As regards this second edition, first of all I am glad to say that after five and twenty years I find nothing to retract; so that my fundamental convictions have only been confirmed, as far as concerns myself at least. The alterations in the first volume therefore, which contains the whole text of the first edition, nowhere touch what is essential. Sometimes they concern things of merely secondary importance, and more often consist of very short explanatory additions inserted here and there. Only the criticism of the Kantian philosophy has received important corrections and large additions, for these could not be put into a supplementary book, such as those which are given in the second volume, and which correspond to each of the four books that contain the exposition of my own doctrine. In the case of the latter, I have chosen this form of enlarging and improving them, because the five and twenty years that have passed since they were composed have produced so marked a change in my method of exposition

and in my style, that it would not have done to combine the content of the second volume with that of the first, as both must have suffered by the fusion. I therefore give both works separately, and in the earlier exposition, even in many places where I would now express myself quite differently, I have changed nothing, because I desired to guard against spoiling the work of my earlier years through the carping criticism of age. What in this regard might need correction will correct itself in the mind of the reader with the help of the second volume. Both volumes have, in the full sense of the word, a supplementary relation to each other, so far as this rests on the fact that one age of human life is, intellectually, the supplement of another. It will therefore be found, not only that each volume contains what the other lacks, but that the merits of the one consist peculiarly in that which is wanting in the other. Thus, if the first half of my work surpasses the second in what can only be supplied by the fire of youth and the energy of first conceptions, the second will surpass the first by the ripeness and complete elaboration of the thought which can only belong to the fruit of the labour of a long life. For when I had the strength originally to grasp the fundamental thought of my system, to follow it at once into its four branches, to return from them to the unity of their origin, and then to explain the whole distinctly, I could not yet be in a position to work out all the branches of the system with the fulness, thoroughness, and elaborateness which is only reached by the meditation of many years — meditation which is required to test and illustrate the system by innumerable facts, to support it by the most different kinds of proof, to throw light on it from all sides, and then to place the different points of view boldly in contrast, to separate thoroughly the multifarious materials, and present them in a well-arranged whole. Therefore, although it would, no doubt, have been more agreeable to the reader to have my whole work in one piece, instead of consisting, as it now does, of two halves, which must be combined in using them, he must reflect that this would have demanded that I should accomplish at one period of life what it is only possible to accomplish in two, for I would have had to possess the qualities at one period of life that nature has divided between two quite different ones. Hence the necessity of presenting my work in two halves supplementary to each other may be compared to the necessity in consequence of which a chromatic object-glass, which cannot be made out of one piece, is produced by joining together a convex lens of flint glass and a concave lens of crown

glass, the combined effect of which is what was sought. Yet, on the other hand, the reader will find some compensation for the inconvenience of using two volumes at once, in the variety and the relief which is afforded by the handling of the same subject, by the same mind, in the same spirit, but in very different years. However, it is very advisable that those who are not yet acquainted with my philosophy should first of all read the first volume without using the supplementary books, and should make use of these only on a second perusal; otherwise it would be too difficult for them to grasp the system in its connection. For it is only thus explained in the first volume, while the second is devoted to a more detailed investigation and a complete development of the individual doctrines. Even those who should not make up their minds to a second reading of the first volume had better not read the second volume till after the first, and then for itself, in the ordinary sequence of its chapters, which, at any rate, stand in some kind of connection, though a somewhat looser one, the gaps of which they will fully supply by the recollection of the first volume, if they have thoroughly comprehended it. Besides, they will find everywhere the reference to the corresponding passages of the first volume, the paragraphs of which I have numbered in the second edition for this purpose, though in the first edition they were only divided by lines.

I have already explained in the preface to the first edition, that my philosophy is founded on that of Kant, and therefore presupposes a thorough knowledge of it. I repeat this here. For Kant's teaching produces in the mind of every one who has comprehended it a fundamental change which is so great that it may be regarded as an intellectual new-birth. It alone is able really to remove the inborn realism which proceeds from the original character of the intellect, which neither Berkeley nor Malebranche succeed in doing, for they remain too much in the universal, while Kant goes into the particular, and indeed in a way that is quite unexampled both before and after him, and which has quite a peculiar, and, we might say, immediate effect upon the mind in consequence of which it undergoes a complete undeception, and forthwith looks at all things in another light. Only in this way can any one become susceptible to the more positive expositions which I have to give. On the other hand, he who has not mastered the Kantian philosophy, whatever else he may have studied, is, as it were, in a state of innocence; that is to say, he remains in the grasp of that natural and childish realism in which we are all born, and which fits us for

everything possible, with the single exception of philosophy. Such a man then stands to the man who knows the Kantian philosophy as a minor to a man of full age. That this truth should nowadays sound paradoxical, which would not have been the case in the first thirty years after the appearance of the Critique of Reason, is due to the fact that a generation has grown up that does not know Kant properly, because it has never heard more of him than a hasty, impatient lecture, or an account at second-hand; and this again is due to the fact that in consequence of bad guidance, this generation has wasted its time with the philosophemes of vulgar, uncalled men, or even of bombastic sophists, which are unwarrantably commended to it. Hence the confusion of fundamental conceptions, and in general the unspeakable crudeness and awkwardness that appears from under the covering of affectation and pretentiousness in the philosophical attempts of the generation thus brought up. But whoever thinks he can learn Kant's philosophy from the exposition of others makes a terrible mistake. Nay, rather I must earnestly warn against such accounts, especially the more recent ones; and indeed in the years just past I have met with expositions of the Kantian philosophy in the writings of the Hegelians which actually reach the incredible. How should the minds that in the freshness of youth have been strained and ruined by the nonsense of Hegelism, be still capable of following Kant's profound investigations? They are early accustomed to take the hollowest jingle of words for philosophical thoughts, the most miserable sophisms for acuteness, and silly conceits for dialectic, and their minds are disorganised through the admission of mad combinations of words to which the mind torments and exhausts itself in vain to attach some thought. No Critique of Reason can avail them, no philosophy, they need a *medicina mentis*, first as a sort of purgative, *un petit cours de senscommunologie*, and then one must further see whether, in their case, there can even be any talk of philosophy. The Kantian doctrine then will be sought for in vain anywhere else but in Kant's own works; but these are throughout instructive, even where he errs, even where he fails. In consequence of his originality, it holds good of him in the highest degree, as indeed of all true philosophers, that one can only come to know them from their own works, not from the accounts of others. For the thoughts of any extraordinary intellect cannot stand being filtered through the vulgar mind. Born behind the broad, high, finely-arched brow, from under which shine beaming eyes, they lose all power and life, and appear no longer like

themselves, when removed to the narrow lodging and low roofing of the confined, contracted, thick-walled skull from which dull glances steal directed to personal ends. Indeed we may say that minds of this kind act like an uneven glass, in which everything is twisted and distorted, loses the regularity of its beauty, and becomes a caricature. Only from their authors themselves can we receive philosophical thoughts; therefore whoever feels himself drawn to philosophy must himself seek out its immortal teachers in the still sanctuary of their works. The principal chapters of any one of these true philosophers will afford a thousand times more insight into their doctrines than the heavy and distorted accounts of them that everyday men produce, who are still for the most part deeply entangled in the fashionable philosophy of the time, or in the sentiments of their own minds. But it is astonishing how decidedly the public seizes by preference on these expositions at second-hand. It seems really as if elective affinities were at work here, by virtue of which the common nature is drawn to its like, and therefore will rather hear what a great man has said from one of its own kind. Perhaps this rests on the same principle as that of mutual instruction, according to which children learn best from children.

One word more for the professors of philosophy. I have always been compelled to admire not merely the sagacity, the true and fine tact with which, immediately on its appearance, they recognised my philosophy as something altogether different from and indeed dangerous to their own attempts, or, in popular language, something that would not suit their turn; but also the sure and astute policy by virtue of which they at once discovered the proper procedure with regard to it, the complete harmony with which they applied it, and the persistency with which they have remained faithful to it. This procedure, which further commended itself by the great ease of carrying it out, consists, as is well known, in altogether ignoring and thus in secreting — according to Goethe's malicious phrase, which just means the appropriating of what is of weight and significance. The efficiency of this quiet means is increased by the Corybantic shouts with which those who are at one reciprocally greet the birth of their own spiritual children — shouts which compel the public to look and note the air of importance with which they congratulate themselves on the event. Who can mistake the object of such proceedings? Is there then nothing to oppose to the maxim, *primum vivere, deinde philosophari*? These

gentlemen desire to live, and indeed to live by philosophy. To philosophy they are assigned with their wives and children, and in spite of Petrarch's *povera e nuda vai filosofia*, they have staked everything upon it. Now my philosophy is by no means so constituted that any one can live by it. It lacks the first indispensable requisite of a well-paid professional philosophy, a speculative theology, which — in spite of the troublesome Kant with his Critique of Reason — should and must, it is supposed, be the chief theme of all philosophy, even if it thus takes on itself the task of talking straight on of that of which it can know absolutely nothing. Indeed my philosophy does not permit to the professors the fiction they have so cunningly devised, and which has become so indispensable to them, of a reason that knows, perceives, or apprehends immediately and absolutely. This is a doctrine which it is only necessary to impose upon the reader at starting, in order to pass in the most comfortable manner in the world, as it were in a chariot and four, into that region beyond the possibility of all experience, which Kant has wholly and for ever shut out from our knowledge, and in which are found immediately revealed and most beautifully arranged the fundamental dogmas of modern, Judaising, optimistic Christianity. Now what in the world has my subtle philosophy, deficient as it is in these essential requisites, with no intentional aim, and unable to afford a means of subsistence, whose pole star is truth alone the naked, unrewarded, unbefriended, often persecuted truth, and which steers straight for it without looking to the right hand or the left, — what, I say, has this to do with that *alma mater*, the good, well-to-do university philosophy which, burdened with a hundred aims and a thousand motives, comes on its course cautiously tacking, while it keeps before its eyes at all times the fear of the Lord, the will of the ministry, the laws of the established church, the wishes of the publisher, the attendance of the students, the goodwill of colleagues, the course of current politics, the momentary tendency of the public, and Heaven knows what besides? Or what has my quiet, earnest search for truth in common with the noisy scholastic disputations of the chair and the benches, the inmost motives of which are always personal aims. The two kinds of philosophy are, indeed, radically different. Thus it is that with me there is no compromise and no fellowship, that no one reaps any benefit from my works but the man who seeks the truth alone, and therefore none of the philosophical parties of the day; for they all follow their own aims, while I have only insight into truth to offer, which suits none of these aims,

because it is not modelled after any of them. If my philosophy is to become susceptible of professorial exposition, the times must entirely change. What a pretty thing it would be if a philosophy by which nobody could live were to gain for itself light and air, not to speak of the general ear! This must be guarded against, and all must oppose it as one man. But it is not just such an easy game to controvert and refute; and, moreover, these are mistaken means to employ, because they just direct the attention of the public to the matter, and its taste for the lucubrations of the professors of philosophy might be destroyed by the perusal of my writings. For whoever has tasted of earnest will not relish jest, especially when it is tiresome. Therefore the silent system, so unanimously adopted, is the only right one, and I can only advise them to stick to it and go on with it as long as it will answer, that is, until to ignore is taken to imply ignorance; then there will just be time to turn back. Meanwhile it remains open to every one to pluck out a small feather here and there for his own use, for the superfluity of thoughts at home should not be very oppressive. Thus the ignoring and silent system may hold out a good while, at least the span of time I may have yet to live, whereby much is already won. And if, in the meantime, here and there an indiscreet voice has let itself be heard, it is soon drowned by the loud talking of the professors, who, with important airs, know how to entertain the public with very different things. I advise, however, that the unanimity of procedure should be somewhat more strictly observed, and especially that the young men should be looked after, for they are sometimes so fearfully indiscreet. For even so I cannot guarantee that the commended procedure will last for ever, and cannot answer for the final issue. It is a nice question as to the steering of the public, which, on the whole, is good and tractable. Although we nearly at all times see the Gorgiases and the Hippiases uppermost, although the absurd, as a rule, predominates, and it seems impossible that the voice of the individual can ever penetrate through the chorus of the befooling and the befooled, there yet remains to the genuine works of every age a quite peculiar, silent, slow, and powerful influence; and, as if by a miracle, we see them rise at last out of the turmoil like a balloon that floats up out of the thick atmosphere of this globe into purer regions, where, having once arrived, it remains at rest, and no one can draw it down again.

Written at Frankfort-on-the-Maine in February 1844.

First Book. The World As Idea.

First Aspect. The Idea Subordinated To The Principle Of Sufficient Reason: The Object Of Experience And Science.

Sors de l'enfance, ami réveille toi!
— *Jean Jacques Rousseau.*

§ 1. "The world is my idea:" — this is a truth which holds good for everything that lives and knows, though man alone can bring it into reflective and abstract consciousness. If he really does this, he has attained to philosophical wisdom. It then becomes clear and certain to him that what he knows is not a sun and an earth, but only an eye that sees a sun, a hand that feels an earth; that the world which surrounds him is there only as idea, *i.e.*, only in relation to something else, the consciousness, which is himself. If any truth can be asserted *a priori*, it is this: for it is the expression of the most general form of all possible and thinkable experience: a form which is more general than time, or space, or causality, for they all presuppose it; and each of these, which we have seen to be just so many modes of the principle of sufficient reason, is valid only for a particular class of ideas; whereas the antithesis of object and subject is the common form of all these classes, is that form under which alone any idea of whatever kind it may be, abstract or intuitive, pure or empirical, is possible and thinkable. No truth therefore is more certain, more independent of all others, and less in need of proof than this, that all that exists for knowledge, and therefore this whole world, is only object in relation to subject, perception of a perceiver, in a word, idea. This is obviously true of the past and the future, as well as of the present, of what is farthest off, as of what is near; for it is true of time and space themselves, in which alone these distinctions arise. All that in any way belongs or can belong to the world is inevitably thus conditioned through the subject, and exists only for the subject. The world is idea.

This truth is by no means new. It was implicitly involved in the sceptical reflections from which Descartes started. Berkeley, however, was the first who distinctly enunciated it, and by this he has rendered a permanent service to philosophy, even though the rest of his teaching should not endure. Kant's primary mistake was the neglect of this principle, as is shown in the appendix. How early again this truth was recognised by the wise men of India, appearing indeed as the fundamental tenet of the

Vedânta philosophy ascribed to Vyasa, is pointed out by Sir William Jones in the last of his essays: "On the philosophy of the Asiatics" (Asiatic Researches, vol. iv. p. 164), where he says, "The fundamental tenet of the Vedanta school consisted not in denying the existence of matter, that is, of solidity, impenetrability, and extended figure (to deny which would be lunacy), but in correcting the popular notion of it, and in contending that it has no essence independent of mental perception; that existence and perceptibility are convertible terms." These words adequately express the compatibility of empirical reality and transcendental ideality.

In this first book, then, we consider the world only from this side, only so far as it is idea. The inward reluctance with which any one accepts the world as merely his idea, warns him that this view of it, however true it may be, is nevertheless one-sided, adopted in consequence of some arbitrary abstraction. And yet it is a conception from which he can never free himself. The defectiveness of this view will be corrected in the next book by means of a truth which is not so immediately certain as that from which we start here; a truth at which we can arrive only by deeper research and more severe abstraction, by the separation of what is different and the union of what is identical. This truth, which must be very serious and impressive if not awful to every one, is that a man can also say and must say, "the world is my will."

In this book, however, we must consider separately that aspect of the world from which we start, its aspect as knowable, and therefore, in the meantime, we must, without reserve, regard all presented objects, even our own bodies (as we shall presently show more fully), merely as ideas, and call them merely ideas. By so doing we always abstract from will (as we hope to make clear to every one further on), which by itself constitutes the other aspect of the world. For as the world is in one aspect entirely *idea*, so in another it is entirely *will*. A reality which is neither of these two, but an object in itself (into which the thing in itself has unfortunately dwindled in the hands of Kant), is the phantom of a dream, and its acceptance is an *ignis fatuus* in philosophy.

§ 2. That which knows all things and is known by none is the subject. Thus it is the supporter of the world, that condition of all phenomena, of all objects which is always pre-supposed throughout experience; for all that exists, exists only for the subject. Every one finds himself to be subject, yet only in so far as he knows, not in so far as he is an object of knowledge. But

his body is object, and therefore from this point of view we call it idea. For the body is an object among objects, and is conditioned by the laws of objects, although it is an immediate object. Like all objects of perception, it lies within the universal forms of knowledge, time and space, which are the conditions of multiplicity. The subject, on the contrary, which is always the knower, never the known, does not come under these forms, but is presupposed by them; it has therefore neither multiplicity nor its opposite unity. We never know it, but it is always the knower wherever there is knowledge.

So then the world as idea, the only aspect in which we consider it at present, has two fundamental, necessary, and inseparable halves. The one half is the object, the forms of which are space and time, and through these multiplicity. The other half is the subject, which is not in space and time, for it is present, entire and undivided, in every percipient being. So that any one percipient being, with the object, constitutes the whole world as idea just as fully as the existing millions could do; but if this one were to disappear, then the whole world as idea would cease to be. These halves are therefore inseparable even for thought, for each of the two has meaning and existence only through and for the other, each appears with the other and vanishes with it. They limit each other immediately; where the object begins the subject ends. The universality of this limitation is shown by the fact that the essential and hence universal forms of all objects, space, time, and causality, may, without knowledge of the object, be discovered and fully known from a consideration of the subject, *i.e.*, in Kantian language, they lie *a priori* in our consciousness. That he discovered this is one of Kant's principal merits, and it is a great one. I however go beyond this, and maintain that the principle of sufficient reason is the general expression for all these forms of the object of which we are *a priori* conscious; and that therefore all that we know purely *a priori*, is merely the content of that principle and what follows from it; in it all our certain *a priori* knowledge is expressed. In my essay on the principle of sufficient reason I have shown in detail how every possible object comes under it; that is, stands in a necessary relation to other objects, on the one side as determined, on the other side as determining: this is of such wide application, that the whole existence of all objects, so far as they are objects, ideas and nothing more, may be entirely traced to this their necessary relation to each other, rests only in it, is in fact merely relative; but of this more presently. I have

further shown, that the necessary relation which the principle of sufficient reason expresses generally, appears in other forms corresponding to the classes into which objects are divided, according to their possibility; and again that by these forms the proper division of the classes is tested. I take it for granted that what I said in this earlier essay is known and present to the reader, for if it had not been already said it would necessarily find its place here.

§ 3. The chief distinction among our ideas is that between ideas of perception and abstract ideas. The latter form just one class of ideas, namely concepts, and these are the possession of man alone of all creatures upon earth. The capacity for these, which distinguishes him from all the lower animals, has always been called reason.[5] We shall consider these abstract ideas by themselves later, but, in the first place, we shall speak exclusively of the *ideas of perception*. These comprehend the whole visible world, or the sum total of experience, with the conditions of its possibility. We have already observed that it is a highly important discovery of Kant's, that these very conditions, these forms of the visible world, *i.e.*, the absolutely universal element in its perception, the common property of all its phenomena, space and time, even when taken by themselves and apart from their content, can, not only be thought in the abstract, but also be directly perceived; and that this perception or intuition is not some kind of phantasm arising from constant recurrence in experience, but is so entirely independent of experience that we must rather regard the latter as dependent on it, inasmuch as the qualities of space and time, as they are known in *a priori* perception or intuition, are valid for all possible experience, as rules to which it must invariably conform. Accordingly, in my essay on the principle of sufficient reason, I have treated space and time, because they are perceived as pure and empty of content, as a special and independent class of ideas. This quality of the universal forms of intuition, which was discovered by Kant, that they may be perceived in themselves and apart from experience, and that they may be known as exhibiting those laws on which is founded the infallible science of mathematics, is certainly very important. Not less worthy of remark, however, is this other quality of time and space, that the principle of sufficient reason, which conditions experience as the law of causation and of motive, and thought as the law of the basis of judgment, appears here in quite a special form, to which I have given the name of the ground of being. In time, this is the succession of its

moments, and in space the position of its parts, which reciprocally determine each other *ad infinitum*.

Any one who has fully understood from the introductory essay the complete identity of the content of the principle of sufficient reason in all its different forms, must also be convinced of the importance of the knowledge of the simplest of these forms, as affording him insight into his own inmost nature. This simplest form of the principle we have found to be time. In it each instant is, only in so far as it has effaced the preceding one, its generator, to be itself in turn as quickly effaced. The past and the future (considered apart from the consequences of their content) are empty as a dream, and the present is only the indivisible and unenduring boundary between them. And in all the other forms of the principle of sufficient reason, we shall find the same emptiness, and shall see that not time only but also space, and the whole content of both of them, *i.e.*, all that proceeds from causes and motives, has a merely relative existence, is only through and for another like to itself, *i.e.*, not more enduring. The substance of this doctrine is old: it appears in Heraclitus when he laments the eternal flux of things; in Plato when he degrades the object to that which is ever becoming, but never being; in Spinoza as the doctrine of the mere accidents of the one substance which is and endures. Kant opposes what is thus known as the mere phenomenon to the thing in itself. Lastly, the ancient wisdom of the Indian philosophers declares, "It is Mâyâ, the veil of deception, which blinds the eyes of mortals, and makes them behold a world of which they cannot say either that it is or that it is not: for it is like a dream; it is like the sunshine on the sand which the traveller takes from afar for water, or the stray piece of rope he mistakes for a snake." (These similes are repeated in innumerable passages of the Vedas and the Puranas.) But what all these mean, and that of which they all speak, is nothing more than what we have just considered — the world as idea subject to the principle of sufficient reason.

§ 4. Whoever has recognised the form of the principle of sufficient reason, which appears in pure time as such, and on which all counting and arithmetical calculation rests, has completely mastered the nature of time. Time is nothing more than that form of the principle of sufficient reason, and has no further significance. Succession is the form of the principle of sufficient reason in time, and succession is the whole nature of time. Further, whoever has recognised the principle of sufficient reason as it

appears in the presentation of pure space, has exhausted the whole nature of space, which is absolutely nothing more than that possibility of the reciprocal determination of its parts by each other, which is called position. The detailed treatment of this, and the formulation in abstract conceptions of the results which flow from it, so that they may be more conveniently used, is the subject of the science of geometry. Thus also, whoever has recognised the law of causation, the aspect of the principle of sufficient reason which appears in what fills these forms (space and time) as objects of perception, that is to say matter, has completely mastered the nature of matter as such, for matter is nothing more than causation, as any one will see at once if he reflects. Its true being is its action, nor can we possibly conceive it as having any other meaning. Only as active does it fill space and time; its action upon the immediate object (which is itself matter) determines that perception in which alone it exists. The consequence of the action of any material object upon any other, is known only in so far as the latter acts upon the immediate object in a different way from that in which it acted before; it consists only of this. Cause and effect thus constitute the whole nature of matter; its true being is its action. (A fuller treatment of this will be found in the essay on the Principle of Sufficient Reason, § 21, p. 77.) The nature of all material things is therefore very appropriately called in German *Wirklichkeit*,[6] a word which is far more expressive than *Realität*. Again, that which is acted upon is always matter, and thus the whole being and essence of matter consists in the orderly change, which one part of it brings about in another part. The existence of matter is therefore entirely relative, according to a relation which is valid only within its limits, as in the case of time and space.

But time and space, each for itself, can be mentally presented apart from matter, whereas matter cannot be so presented apart from time and space. The form which is inseparable from it presupposes space, and the action in which its very existence consists, always imports some change, in other words a determination in time. But space and time are not only, each for itself, presupposed by matter, but a union of the two constitutes its essence, for this, as we have seen, consists in action, *i.e.*, in causation. All the innumerable conceivable phenomena and conditions of things, might be coexistent in boundless space, without limiting each other, or might be successive in endless time without interfering with each other: thus a necessary relation of these phenomena to each other, and a law which

should regulate them according to such a relation, is by no means needful, would not, indeed, be applicable: it therefore follows that in the case of all co-existence in space and change in time, so long as each of these forms preserves for itself its condition and its course without any connection with the other, there can be no causation, and since causation constitutes the essential nature of matter, there can be no matter. But the law of causation receives its meaning and necessity only from this, that the essence of change does not consist simply in the mere variation of things, but rather in the fact that at the *same part of space* there is now *one thing* and then *another*, and at *one* and the same point of time there is *here* one thing and there *another*: only this reciprocal limitation of space and time by each other gives meaning, and at the same time necessity, to a law, according to which change must take place. What is determined by the law of causality is therefore not merely a succession of things in time, but this succession with reference to a definite space, and not merely existence of things in a particular place, but in this place at a different point of time. Change, *i.e.*, variation which takes place according to the law of causality, implies always a determined part of space and a determined part of time together and in union. Thus causality unites space with time. But we found that the whole essence of matter consisted in action, *i.e.*, in causation, consequently space and time must also be united in matter, that is to say, matter must take to itself at once the distinguishing qualities both of space and time, however much these may be opposed to each other, and must unite in itself what is impossible for each of these independently, that is, the fleeting course of time, with the rigid unchangeable perduration of space: infinite divisibility it receives from both. It is for this reason that we find that co-existence, which could neither be in time alone, for time has no contiguity, nor in space alone, for space has no before, after, or now, is first established through matter. But the co-existence of many things constitutes, in fact, the essence of reality, for through it permanence first becomes possible; for permanence is only knowable in the change of something which is present along with what is permanent, while on the other hand it is only because something permanent is present along with what changes, that the latter gains the special character of change, *i.e.*, the mutation of quality and form in the permanence of substance, that is to say, in matter.[7] If the world were in space alone, it would be rigid and immovable, without succession, without change, without action; but we know that with action, the idea of

matter first appears. Again, if the world were in time alone, all would be fleeting, without persistence, without contiguity, hence without co-existence, and consequently without permanence; so that in this case also there would be no matter. Only through the union of space and time do we reach matter, and matter is the possibility of co-existence, and, through that, of permanence; through permanence again matter is the possibility of the persistence of substance in the change of its states.[8] As matter consists in the union of space and time, it bears throughout the stamp of both. It manifests its origin in space, partly through the form which is inseparable from it, but especially through its persistence (substance), the *a priori* certainty of which is therefore wholly deducible from that of space[9] (for variation belongs to time alone, but in it alone and for itself nothing is persistent). Matter shows that it springs from time by quality (accidents), without which it never exists, and which is plainly always causality, action upon other matter, and therefore change (a time concept). The law of this action, however, always depends upon space and time together, and only thus obtains meaning. The regulative function of causality is confined entirely to the determination of what must occupy *this time and this space*. The fact that we know *a priori* the unalterable characteristics of matter, depends upon this derivation of its essential nature from the forms of our knowledge of which we are conscious *a priori*. These unalterable characteristics are space-occupation, *i.e.*, impenetrability, *i.e.*, causal action, consequently, extension, infinite divisibility, persistence, *i.e.*, indestructibility, and lastly mobility: weight, on the other hand, notwithstanding its universality, must be attributed to *a posteriori* knowledge, although Kant, in his “Metaphysical Introduction to Natural Philosophy,” p. 71 (p. 372 of Rosenkranz’s edition), treats it as knowable *a priori*.

But as the object in general is only for the subject, as its idea, so every special class of ideas is only for an equally special quality in the subject, which is called a faculty of perception. This subjective correlative of time and space in themselves as empty forms, has been named by Kant pure sensibility; and we may retain this expression, as Kant was the first to treat of the subject, though it is not exact, for sensibility presupposes matter. The subjective correlative of matter or of causation, for these two are the same, is understanding, which is nothing more than this. To know causality is its one function, its only power; and it is a great one, embracing much, of

manifold application, yet of unmistakable identity in all its manifestations. Conversely all causation, that is to say, all matter, or the whole of reality, is only for the understanding, through the understanding, and in the understanding. The first, simplest, and ever-present example of understanding is the perception of the actual world. This is throughout knowledge of the cause from the effect, and therefore all perception is intellectual. The understanding could never arrive at this perception, however, if some effect did not become known immediately, and thus serve as a starting-point. But this is the affection of the animal body. So far, then, the animal body is the *immediate object* of the subject; the perception of all other objects becomes possible through it. The changes which every animal body experiences, are immediately known, that is, felt; and as these effects are at once referred to their causes, the perception of the latter as *objects* arises. This relation is no conclusion in abstract conceptions; it does not arise from reflection, nor is it arbitrary, but immediate, necessary, and certain. It is the method of knowing of the pure understanding, without which there could be no perception; there would only remain a dull plant-like consciousness of the changes of the immediate object, which would succeed each other in an utterly unmeaning way, except in so far as they might have a meaning for the will either as pain or pleasure. But as with the rising of the sun the visible world appears, so at one stroke, the understanding, by means of its one simple function, changes the dull, meaningless sensation into perception. What the eye, the ear, or the hand feels, is not perception; it is merely its data. By the understanding passing from the effect to the cause, the world first appears as perception extended in space, varying in respect of form, persistent through all time in respect of matter; for the understanding unites space and time in the idea of matter, that is, causal action. As the world as idea exists only through the understanding, so also it exists only for the understanding. In the first chapter of my essay on "Light and Colour," I have already explained how the understanding constructs perceptions out of the data supplied by the senses; how by comparison of the impressions which the various senses receive from the object, a child arrives at perceptions; how this alone affords the solution of so many phenomena of the senses; the single vision of two eyes, the double vision in the case of a squint, or when we try to look at once at objects which lie at unequal distances behind each other; and all illusion which is produced by a sudden alteration in the organs of sense. But

I have treated this important subject much more fully and thoroughly in the second edition of the essay on “The Principle of Sufficient Reason,” § 21. All that is said there would find its proper place here, and would therefore have to be said again; but as I have almost as much disinclination to quote myself as to quote others, and as I am unable to explain the subject better than it is explained there, I refer the reader to it, instead of quoting it, and take for granted that it is known.

The process by which children, and persons born blind who have been operated upon, learn to see, the single vision of the double sensation of two eyes, the double vision and double touch which occur when the organs of sense have been displaced from their usual position, the upright appearance of objects while the picture on the retina is upside down, the attributing of colour to the outward objects, whereas it is merely an inner function, a division through polarisation, of the activity of the eye, and lastly the stereoscope, — all these are sure and incontrovertible evidence that perception is not merely of the senses, but intellectual — that is, *pure knowledge through the understanding of the cause from the effect*, and that, consequently, it presupposes the law of causality, in a knowledge of which all perception — that is to say all experience, by virtue of its primary and only possibility, depends. The contrary doctrine that the law of causality results from experience, which was the scepticism of Hume, is first refuted by this. For the independence of the knowledge of causality of all experience, — that is, its *a priori* character — can only be deduced from the dependence of all experience upon it; and this deduction can only be accomplished by proving, in the manner here indicated, and explained in the passages referred to above, that the knowledge of causality is included in perception in general, to which all experience belongs, and therefore in respect of experience is completely *a priori*, does not presuppose it, but is presupposed by it as a condition. This, however, cannot be deduced in the manner attempted by Kant, which I have criticised in the essay on “The Principle of Sufficient Reason,” § 23.

§ 5. It is needful to guard against the grave error of supposing that because perception arises through the knowledge of causality, the relation of subject and object is that of cause and effect. For this relation subsists only between the immediate object and objects known indirectly, thus always between objects alone. It is this false supposition that has given rise to the foolish controversy about the reality of the outer world; a controversy

in which dogmatism and scepticism oppose each other, and the former appears, now as realism, now as idealism. Realism treats the object as cause, and the subject as its effect. The idealism of Fichte reduces the object to the effect of the subject. Since however, and this cannot be too much emphasised, there is absolutely no relation according to the principle of sufficient reason between subject and object, neither of these views could be proved, and therefore scepticism attacked them both with success. Now, just as the law of causality precedes perception and experience as their condition, and therefore cannot (as Hume thought) be derived from them, so object and subject precede all knowledge, and hence the principle of sufficient reason in general, as its first condition; for this principle is merely the form of all objects, the whole nature and possibility of their existence as phenomena: but the object always presupposes the subject; and therefore between these two there can be no relation of reason and consequent. My essay on the principle of sufficient reason accomplishes just this: it explains the content of that principle as the essential form of every object — that is to say, as the universal nature of all objective existence, as something which pertains to the object as such; but the object as such always presupposes the subject as its necessary correlative; and therefore the subject remains always outside the province in which the principle of sufficient reason is valid. The controversy as to the reality of the outer world rests upon this false extension of the validity of the principle of sufficient reason to the subject also, and starting with this mistake it can never understand itself. On the one side realistic dogmatism, looking upon the idea as the effect of the object, desires to separate these two, idea and object, which are really one, and to assume a cause quite different from the idea, an object in itself, independent of the subject, a thing which is quite inconceivable; for even as object it presupposes subject, and so remains its idea. Opposed to this doctrine is scepticism, which makes the same false presupposition that in the idea we have only the effect, never the cause, therefore never real being; that we always know merely the action of the object. But this object, it supposes, may perhaps have no resemblance whatever to its effect, may indeed have been quite erroneously received as the cause, for the law of causality is first to be gathered from experience, and the reality of experience is then made to rest upon it. Thus both of these views are open to the correction, firstly, that object and idea are the same; secondly, that the true being of the object of perception is its action, that the reality of the

thing consists in this, and the demand for an existence of the object outside the idea of the subject, and also for an essence of the actual thing different from its action, has absolutely no meaning, and is a contradiction: and that the knowledge of the nature of the effect of any perceived object, exhausts such an object itself, so far as it is object, *i.e.*, idea, for beyond this there is nothing more to be known. So far then, the perceived world in space and time, which makes itself known as causation alone, is entirely real, and is throughout simply what it appears to be, and it appears wholly and without reserve as idea, bound together according to the law of causality. This is its empirical reality. On the other hand, all causality is in the understanding alone, and for the understanding. The whole actual, that is, active world is determined as such through the understanding, and apart from it is nothing. This, however, is not the only reason for altogether denying such a reality of the outer world as is taught by the dogmatist, who explains its reality as its independence of the subject. We also deny it, because no object apart from a subject can be conceived without contradiction. The whole world of objects is and remains idea, and therefore wholly and for ever determined by the subject; that is to say, it has transcendental ideality. But it is not therefore illusion or mere appearance; it presents itself as that which it is, idea, and indeed as a series of ideas of which the common bond is the principle of sufficient reason. It is according to its inmost meaning quite comprehensible to the healthy understanding, and speaks a language quite intelligible to it. To dispute about its reality can only occur to a mind perverted by over-subtilty, and such discussion always arises from a false application of the principle of sufficient reason, which binds all ideas together of whatever kind they may be, but by no means connects them with the subject, nor yet with a something which is neither subject nor object, but only the ground of the object; an absurdity, for only objects can be and always are the ground of objects. If we examine more closely the source of this question as to the reality of the outer world, we find that besides the false application of the principle of sufficient reason generally to what lies beyond its province, a special confusion of its forms is also involved; for that form which it has only in reference to concepts or abstract ideas, is applied to perceived ideas, real objects; and a ground of knowing is demanded of objects, whereas they can have nothing but a ground of being. Among the abstract ideas, the concepts united in the judgment, the principle of sufficient reason appears in such a way that each of these has its worth, its validity, and its whole

existence, here called *truth*, simply and solely through the relation of the judgment to something outside of it, its ground of knowledge, to which there must consequently always be a return. Among real objects, ideas of perception, on the other hand, the principle of sufficient reason appears not as the principle of the ground of *knowing*, but of *being*, as the law of causality: every real object has paid its debt to it, inasmuch as it has come to be, *i.e.*, has appeared as the effect of a cause. The demand for a ground of knowing has therefore here no application and no meaning, but belongs to quite another class of things. Thus the world of perception raises in the observer no question or doubt so long as he remains in contact with it: there is here neither error nor truth, for these are confined to the province of the abstract — the province of reflection. But here the world lies open for sense and understanding; presents itself with naive truth as that which it really is — ideas of perception which develop themselves according to the law of causality.

So far as we have considered the question of the reality of the outer world, it arises from a confusion which amounts even to a misunderstanding of reason itself, and therefore thus far, the question could be answered only by explaining its meaning. After examination of the whole nature of the principle of sufficient reason, of the relation of subject and object, and the special conditions of sense perception, the question itself disappeared because it had no longer any meaning. There is, however, one other possible origin of this question, quite different from the purely speculative one which we have considered, a specially empirical origin, though the question is always raised from a speculative point of view, and in this form it has a much more comprehensible meaning than it had in the first. We have dreams; may not our whole life be a dream? or more exactly: is there a sure criterion of the distinction between dreams and reality? between phantasms and real objects? The assertion that what is dreamt is less vivid and distinct than what we actually perceive is not to the point, because no one has ever been able to make a fair comparison of the two; for we can only compare the recollection of a dream with the present reality. Kant answers the question thus: “The connection of ideas among themselves, according to the law of causality, constitutes the difference between real life and dreams.” But in dreams, as well as in real life, everything is connected individually at any rate, in accordance with the principle of sufficient reason in all its forms, and this connection is broken only between life and dreams,

or between one dream and another. Kant's answer therefore could only run thus: — the *long* dream (life) has throughout complete connection according to the principle of sufficient reason; it has not this connection, however, with *short* dreams, although each of these has in itself the same connection: the bridge is therefore broken between the former and the latter, and on this account we distinguish them.

But to institute an inquiry according to this criterion, as to whether something was dreamt or seen, would always be difficult and often impossible. For we are by no means in a position to trace link by link the causal connection between any experienced event and the present moment, but we do not on that account explain it as dreamt. Therefore in real life we do not commonly employ that method of distinguishing between dreams and reality. The only sure criterion by which to distinguish them is in fact the entirely empirical one of awaking, through which at any rate the causal connection between dreamed events and those of waking life, is distinctly and sensibly broken off. This is strongly supported by the remark of Hobbes in the second chapter of Leviathan, that we easily mistake dreams for reality if we have unintentionally fallen asleep without taking off our clothes, and much more so when it also happens that some undertaking or design fills all our thoughts, and occupies our dreams as well as our waking moments. We then observe the awaking just as little as the falling asleep, dream and reality run together and become confounded. In such a case there is nothing for it but the application of Kant's criterion; but if, as often happens, we fail to establish by means of this criterion, either the existence of causal connection with the present, or the absence of such connection, then it must for ever remain uncertain whether an event was dreamt or really happened. Here, in fact, the intimate relationship between life and dreams is brought out very clearly, and we need not be ashamed to confess it, as it has been recognised and spoken of by many great men. The Vedas and Puranas have no better simile than a dream for the whole knowledge of the actual world, which they call the web of Mâyâ, and they use none more frequently. Plato often says that men live only in a dream; the philosopher alone strives to awake himself. Pindar says (ii. η. 135): σκιας οναρ ανθρωπος (umbræ somnium homo), and Sophocles: —

Ὁνω γυν ἡμας ουδεν οντας αλλο, πλην
Σιδωλ᾽ ὁσοιπερ ζωμεν, ἠ κουφην σκιαν. — Ajax, 125.

(Nos enim, quicunque vivimus, nihil aliud esse comperio quam simulacra et levem umbram.) Beside which most worthily stands Shakespeare: —

“We are such stuff
As dreams are made on, and our little life
Is rounded with a sleep.” — *Tempest*, Act iv. Sc. 1.

Lastly, Calderon was so deeply impressed with this view of life that he sought to embody it in a kind of metaphysical drama— “Life a Dream.”

After these numerous quotations from the poets, perhaps I also may be allowed to express myself by a metaphor. Life and dreams are leaves of the same book. The systematic reading of this book is real life, but when the reading hours (that is, the day) are over, we often continue idly to turn over the leaves, and read a page here and there without method or connection: often one we have read before, sometimes one that is new to us, but always in the same book. Such an isolated page is indeed out of connection with the systematic study of the book, but it does not seem so very different when we remember that the whole continuous perusal begins and ends just as abruptly, and may therefore be regarded as merely a larger single page.

Thus although individual dreams are distinguished from real life by the fact that they do not fit into that continuity which runs through the whole of experience, and the act of awaking brings this into consciousness, yet that very continuity of experience belongs to real life as its form, and the dream on its part can point to a similar continuity in itself. If, therefore, we consider the question from a point of view external to both, there is no distinct difference in their nature, and we are forced to concede to the poets that life is a long dream.

Let us turn back now from this quite independent empirical origin of the question of the reality of the outer world, to its speculative origin. We found that this consisted, first, in the false application of the principle of sufficient reason to the relation of subject and object; and secondly, in the confusion of its forms, inasmuch as the principle of sufficient reason of knowing was extended to a province in which the principle of sufficient reason of being is valid. But the question could hardly have occupied philosophers so constantly if it were entirely devoid of all real content, and if some true thought and meaning did not lie at its heart as its real source. Accordingly, we must assume that when the element of truth that lies at the bottom of the

question first came into reflection and sought its expression, it became involved in these confused and meaningless forms and problems. This at least is my opinion, and I think that the true expression of that inmost meaning of the question, which it failed to find, is this: — What is this world of perception besides being my idea? Is that of which I am conscious only as idea, exactly like my own body, of which I am doubly conscious, in one aspect as *idea*, in another aspect as *will*? The fuller explanation of this question and its answer in the affirmative, will form the content of the second book, and its consequences will occupy the remaining portion of this work.

§ 6. For the present, however, in this first book we consider everything merely as idea, as object for the subject. And our own body, which is the starting-point for each of us in our perception of the world, we consider, like all other real objects, from the side of its knowableness, and in this regard it is simply an idea. Now the consciousness of every one is in general opposed to the explanation of objects as mere ideas, and more especially to the explanation of our bodies as such; for the thing in itself is known to each of us immediately in so far as it appears as our own body; but in so far as it objectifies itself in the other objects of perception, it is known only indirectly. But this abstraction, this one-sided treatment, this forcible separation of what is essentially and necessarily united, is only adopted to meet the demands of our argument; and therefore the disinclination to it must, in the meantime, be suppressed and silenced by the expectation that the subsequent treatment will correct the one-sidedness of the present one, and complete our knowledge of the nature of the world.

At present therefore the body is for us immediate object; that is to say, that idea which forms the starting-point of the subject's knowledge; because the body, with its immediately known changes, precedes the application of the law of causality, and thus supplies it with its first data. The whole nature of matter consists, as we have seen, in its causal action. But cause and effect exist only for the understanding, which is nothing but their subjective correlative. The understanding, however, could never come into operation if there were not something else from which it starts. This is simple sensation — the immediate consciousness of the changes of the body, by virtue of which it is immediate object. Thus the possibility of knowing the world of perception depends upon two conditions; the first, *objectively expressed*, is the power of material things to act upon each other, to produce changes in

each other, without which common quality of all bodies no perception would be possible, even by means of the sensibility of the animal body. And if we wish to express this condition *subjectively* we say: The understanding first makes perception possible; for the law of causality, the possibility of effect and cause, springs only from the understanding, and is valid only for it, and therefore the world of perception exists only through and for it. The second condition is the sensibility of animal bodies, or the quality of being immediate objects of the subject which certain bodies possess. The mere modification which the organs of sense sustain from without through their specific affections, may here be called ideas, so far as these affections produce neither pain nor pleasure, that is, have no immediate significance for the will, and are yet perceived, exist therefore only for *knowledge*. Thus far, then, I say that the body is immediately *known*, is *immediate object*. But the conception of object is not to be taken here in its fullest sense, for through this immediate knowledge of the body, which precedes the operation of the understanding, and is mere sensation, our own body does not exist specifically as *object*, but first the material things which affect it: for all knowledge of an object proper, of an idea perceived in space, exists only through and for the understanding; therefore not before, but only subsequently to its operation. Therefore the body as object proper, that is, as an idea perceived in space, is first known indirectly, like all other objects, through the application of the law of causality to the action of one of its parts upon another, as, for example, when the eye sees the body or the hand touches it. Consequently the form of our body does not become known to us through mere feeling, but only through knowledge, only in idea; that is to say, only in the brain does our own body first come to appear as extended, articulate, organic. A man born blind receives this idea only little by little from the data afforded by touch. A blind man without hands could never come to know his own form; or at the most could infer and construct it little by little from the effects of other bodies upon him. If, then, we call the body an immediate object, we are to be understood with these reservations.

In other respects, then, according to what has been said, all animal bodies are immediate objects; that is, starting-points for the subject which always knows and therefore is never known in its perception of the world. Thus the distinctive characteristic of animal life is knowledge, with movement following on motives, which are determined by knowledge, just as movement following on stimuli is the distinctive characteristic of plant-

life. Unorganised matter, however, has no movement except such as is produced by causes properly so called, using the term in its narrowest sense. All this I have thoroughly discussed in my essay on the principle of sufficient reason, § 20, in the "Ethics," first essay, iii., and in my work on Sight and Colour, § 1, to which I therefore refer.

It follows from what has been said, that all animals, even the least developed, have understanding; for they all know objects, and this knowledge determines their movements as motive. Understanding is the same in all animals and in all men; it has everywhere the same simple form; knowledge of causality, transition from effect to cause, and from cause to effect, nothing more; but the degree of its acuteness, and the extension of the sphere of its knowledge varies enormously, with innumerable gradations from the lowest form, which is only conscious of the causal connection between the immediate object and objects affecting it — that is to say, perceives a cause as an object in space by passing to it from the affection which the body feels, to the higher grades of knowledge of the causal connection among objects known indirectly, which extends to the understanding of the most complicated system of cause and effect in nature. For even this high degree of knowledge is still the work of the understanding, not of the reason. The abstract concepts of the reason can only serve to take up the objective connections which are immediately known by the understanding, to make them permanent for thought, and to relate them to each other; but reason never gives us immediate knowledge. Every force and law of nature, every example of such forces and laws, must first be immediately known by the understanding, must be apprehended through perception before it can pass into abstract consciousness for reason. Hooke's discovery of the law of gravitation, and the reference of so many important phenomena to this one law, was the work of immediate apprehension by the understanding; and such also was the proof of Newton's calculations, and Lavoisier's discovery of acids and their important function in nature, and also Goethe's discovery of the origin of physical colours. All these discoveries are nothing more than a correct immediate passage from the effect to the cause, which is at once followed by the recognition of the ideality of the force of nature which expresses itself in all causes of the same kind; and this complete insight is just an example of that single function of the understanding, by which an animal perceives as an object in space the cause which affects its body, and differs

from such a perception only in degree. Every one of these great discoveries is therefore, just like perception, an operation of the understanding, an immediate intuition, and as such the work of an instant, an *apperçu*, a flash of insight. They are not the result of a process of abstract reasoning, which only serves to make the immediate knowledge of the understanding permanent for thought by bringing it under abstract concepts, *i.e.*, it makes knowledge distinct, it puts us in a position to impart it and explain it to others. The keenness of the understanding in apprehending the causal relations of objects which are known indirectly, does not find its only application in the sphere of natural science (though all the discoveries in that sphere are due to it), but it also appears in practical life. It is then called good sense or prudence, as in its other application it is better called acuteness, penetration, sagacity. More exactly, good sense or prudence signifies exclusively understanding at the command of the will. But the limits of these conceptions must not be too sharply defined, for it is always that one function of the understanding by means of which all animals perceive objects in space, which, in its keenest form, appears now in the phenomena of nature, correctly inferring the unknown causes from the given effects, and providing the material from which the reason frames general rules as laws of nature; now inventing complicated and ingenious machines by adapting known causes to desired effects; now in the sphere of motives, seeing through and frustrating intrigues and machinations, or fitly disposing the motives and the men who are susceptible to them, setting them in motion, as machines are moved by levers and wheels, and directing them at will to the accomplishment of its ends. Deficiency of understanding is called *stupidity*. It is just *dulness in applying the law of causality*, incapacity for the immediate apprehension of the concatenations of causes and effects, motives and actions. A stupid person has no insight into the connection of natural phenomena, either when they follow their own course, or when they are intentionally combined, *i.e.*, are applied to machinery. Such a man readily believes in magic and miracles. A stupid man does not observe that persons, who apparently act independently of each other, are really in collusion; he is therefore easily mystified, and outwitted; he does not discern the hidden motives of proffered advice or expressions of opinion, &c. But it is always just one thing that he lacks — keenness, rapidity, ease in applying the law of causality, *i.e.*, power of understanding. The greatest, and, in this reference, the most instructive example of

stupidity I ever met with, was the case of a totally imbecile boy of about eleven years of age, in an asylum. He had reason, because he spoke and comprehended, but in respect of understanding he was inferior to many of the lower animals. Whenever I visited him he noticed an eye-glass which I wore round my neck, and in which the window of the room and the tops of the trees beyond were reflected: on every occasion he was greatly surprised and delighted with this, and was never tired of looking at it with astonishment, because he did not understand the immediate causation of reflection.

While the difference in degree of the acuteness of the understanding, is very great between man and man, it is even greater between one species of animal and another. In all species of animals, even those which are nearest to plants, there is at least as much understanding as suffices for the inference from the effect on the immediate object, to the indirectly known object as its cause, *i.e.*, sufficient for perception, for the apprehension of an object. For it is this that constitutes them animals, as it gives them the power of movement following on motives, and thereby the power of seeking for food, or at least of seizing it; whereas plants have only movement following on stimuli, whose direct influence they must await, or else decay, for they cannot seek after them nor appropriate them. We marvel at the great sagacity of the most developed species of animals, such as the dog, the elephant, the monkey or the fox, whose cleverness has been so admirably sketched by Buffon. From these most sagacious animals, we can pretty accurately determine how far understanding can go without reason, *i.e.*, abstract knowledge embodied in concepts. We could not find this out from ourselves, for in us understanding and reason always reciprocally support each other. We find that the manifestation of understanding in animals is sometimes above our expectation, and sometimes below it. On the one hand, we are surprised at the sagacity of the elephant, who, after crossing many bridges during his journey in Europe, once refused to go upon one, because he thought it was not strong enough to bear his weight, though he saw the rest of the party, consisting of men and horses, go upon it as usual. On the other hand, we wonder that the intelligent Orang-outangs, who warm themselves at a fire they have found, do not keep it alight by throwing wood on it; a proof that this requires a deliberation which is not possible without abstract concepts. It is clear that the knowledge of cause and effect, as the universal form of understanding, belongs to all animals *a*

priori, because to them as to us it is the prior condition of all perception of the outer world. If any one desires additional proof of this, let him observe, for example, how a young dog is afraid to jump down from a table, however much he may wish to do so, because he foresees the effect of the weight of his body, though he has not been taught this by experience. In judging of the understanding of animals, we must guard against ascribing to it the manifestations of instinct, a faculty which is quite distinct both from understanding and reason, but the action of which is often very analogous to the combined action of the two. We cannot, however, discuss this here; it will find its proper place in the second book, when we consider the harmony or so-called teleology of nature: and the 27th chapter of the supplementary volume is expressly devoted to it.

Deficiency of *understanding* we call *stupidity*: deficiency in the application of *reason* to practice we shall recognise later as *foolishness*: deficiency of judgment as *silliness*, and lastly, partial or entire deficiency of *memory* as *madness*. But each of these will be considered in its own place. That which is correctly known by *reason* is *truth*, that is, an abstract judgment on sufficient grounds (Essay on the Principle of Sufficient Reason, § 29 and following paragraphs); that which is correctly known by *understanding* is *reality*, that is correct inference from effect on the immediate object to its cause. *Error* is opposed to *truth*, as deception of the *reason*: *illusion* is opposed to *reality*, as deception of the *understanding*. The full discussion of all this will be found in the first chapter of my essay on Light and Colour. Illusion takes place when the same effect may be attributed to two causes, of which one occurs very frequently, the other very seldom; the understanding having no data to decide which of these two causes operates in any particular case, — for their effects are exactly alike, — always assumes the presence of the commoner cause, and as the activity of the understanding is not reflective and discursive, but direct and immediate, this false cause appears before us as a perceived object, whereas it is merely illusion. I have explained in the essay referred to, how in this way double sight and double feeling take place if the organs of sense are brought into an unusual position; and have thus given an incontrovertible proof that perception exists only through and for the understanding. As additional examples of such illusions or deceptions of the understanding, we may mention the broken appearance of a stick dipped in water; the reflections in spherical mirrors, which, when the surface is convex appear

somewhat behind it, and when the surface is concave appear a long way in front of it. To this class also belongs the apparently greater extension of the moon at the horizon than at the zenith. This appearance is not optical, for as the micrometre proves, the eye receives the image of the moon at the zenith, at an even greater angle of vision than at the horizon. The mistake is due to the understanding, which assumes that the cause of the feebler light of the moon and of all stars at the horizon is that they are further off, thus treating them as earthly objects, according to the laws of atmospheric perspective, and therefore it takes the moon to be much larger at the horizon than at the zenith, and also regards the vault of heaven as more extended or flattened out at the horizon. The same false application of the laws of atmospheric perspective leads us to suppose that very high mountains, whose summits alone are visible in pure transparent air, are much nearer than they really are, and therefore not so high as they are; for example, Mont Blanc seen from Salenche. All such illusions are immediately present to us as perceptions, and cannot be dispelled by any arguments of the reason. Reason can only prevent error, that is, a judgment on insufficient grounds, by opposing to it a truth; as for example, the abstract knowledge that the cause of the weaker light of the moon and the stars at the horizon is not greater distance, but the denser atmosphere; but in all the cases we have referred to, the illusion remains in spite of every abstract explanation. For the understanding is in itself, even in the case of man, irrational, and is completely and sharply distinguished from the reason, which is a faculty of knowledge that belongs to man alone. The reason can only *know*; perception remains free from its influence and belongs to the understanding alone.

§ 7. With reference to our exposition up to this point, it must be observed that we did not start either from the object or the subject, but from the idea, which contains and presupposes them both; for the antithesis of object and subject is its primary, universal and essential form. We have therefore first considered this form as such; then (though in this respect reference has for the most part been made to the introductory essay) the subordinate forms of time, space and causality. The latter belong exclusively to the *object*, and yet, as they are essential to the object *as such*, and as the object again is essential to the subject *as such*, they may be discovered from the subject, *i.e.*, they may be known *a priori*, and so far they are to be regarded as the common limits of both. But all these forms

may be referred to one general expression, the principle of sufficient reason, as we have explained in the introductory essay.

This procedure distinguishes our philosophical method from that of all former systems. For they all start either from the object or from the subject, and therefore seek to explain the one from the other, and this according to the principle of sufficient reason. We, on the contrary, deny the validity of this principle with reference to the relation of subject and object, and confine it to the object. It may be thought that the philosophy of identity, which has appeared and become generally known in our own day, does not come under either of the alternatives we have named, for it does not start either from the subject or from the object, but from the absolute, known through "intellectual intuition," which is neither object nor subject, but the identity of the two. I will not venture to speak of this revered identity, and this absolute, for I find myself entirely devoid of all "intellectual intuition." But as I take my stand merely on those manifestoes of the "intellectual intuiter" which are open to all, even to profane persons like myself, I must yet observe that this philosophy is not to be excepted from the alternative errors mentioned above. For it does not escape these two opposite errors in spite of its identity of subject and object, which is not thinkable, but only "intellectually intuitable," or to be experienced by a losing of oneself in it. On the contrary, it combines them both in itself; for it is divided into two parts, firstly, transcendental idealism, which is just Fichte's doctrine of the *ego*, and therefore teaches that the object is produced by the subject, or evolved out of it in accordance with the principle of sufficient reason; secondly, the philosophy of nature, which teaches that the subject is produced little by little from the object, by means of a method called construction, about which I understand very little, yet enough to know that it is a process according to various forms of the principle of sufficient reason. The deep wisdom itself which that construction contains, I renounce; for as I entirely lack "intellectual intuition," all those expositions which presuppose it must for me remain as a book sealed with seven seals. This is so truly the case that, strange to say, I have always been unable to find anything at all in this doctrine of profound wisdom but atrocious and wearisome bombast.

The systems starting from the object had always the whole world of perception and its constitution as their problem; yet the object which they take as their starting-point is not always this whole world of perception, nor

its fundamental element, matter. On the contrary, a division of these systems may be made, based on the four classes of possible objects set forth in the introductory essay. Thus Thales and the Ionic school, Democritus, Epicurus, Giordano Bruno, and the French materialists, may be said to have started from the first class of objects, the real world: Spinoza (on account of his conception of substance, which is purely abstract, and exists only in his definition) and, earlier, the Eleatics, from the second class, the abstract conception: the Pythagoreans and Chinese philosophy in Y-King, from the third class, time, and consequently number: and, lastly, the schoolmen, who teach a creation out of nothing by the act of will of an extra-mundane personal being, started from the fourth class of objects, the act of will directed by knowledge.

Of all systems of philosophy which start from the object, the most consistent, and that which may be carried furthest, is simple materialism. It regards matter, and with it time and space, as existing absolutely, and ignores the relation to the subject in which alone all this really exists. It then lays hold of the law of causality as a guiding principle or clue, regarding it as a self-existent order (or arrangement) of things, *veritas aeterna*, and so fails to take account of the understanding, in which and for which alone causality is. It seeks the primary and most simple state of matter, and then tries to develop all the others from it; ascending from mere mechanism, to chemism, to polarity, to the vegetable and to the animal kingdom. And if we suppose this to have been done, the last link in the chain would be animal sensibility — that is knowledge — which would consequently now appear as a mere modification or state of matter produced by causality. Now if we had followed materialism thus far with clear ideas, when we reached its highest point we would suddenly be seized with a fit of the inextinguishable laughter of the Olympians. As if waking from a dream, we would all at once become aware that its final result — knowledge, which it reached so laboriously, was presupposed as the indispensable condition of its very starting-point, mere matter; and when we imagined that we thought matter, we really thought only the subject that perceives matter; the eye that sees it, the hand that feels it, the understanding that knows it. Thus the tremendous *petitio principii* reveals itself unexpectedly; for suddenly the last link is seen to be the starting-point, the chain a circle, and the materialist is like Baron Münchausen who, when swimming in water on horseback, drew the horse into the air with his legs, and himself also by his cue. The

fundamental absurdity of materialism is that it starts from the *objective*, and takes as the ultimate ground of explanation something *objective*, whether it be matter in the abstract, simply as it is *thought*, or after it has taken form, is empirically given — that is to say, is *substance*, the chemical element with its primary relations. Some such thing it takes, as existing absolutely and in itself, in order that it may evolve organic nature and finally the knowing subject from it, and explain them adequately by means of it; whereas in truth all that is objective is already determined as such in manifold ways by the knowing subject through its forms of knowing, and presupposes them; and consequently it entirely disappears if we think the subject away. Thus materialism is the attempt to explain what is immediately given us by what is given us indirectly. All that is objective, extended, active — that is to say, all that is material — is regarded by materialism as affording so solid a basis for its explanation, that a reduction of everything to this can leave nothing to be desired (especially if in ultimate analysis this reduction should resolve itself into action and reaction). But we have shown that all this is given indirectly and in the highest degree determined, and is therefore merely a relatively present object, for it has passed through the machinery and manufactory of the brain, and has thus come under the forms of space, time and causality, by means of which it is first presented to us as extended in space and ever active in time. From such an indirectly given object, materialism seeks to explain what is immediately given, the idea (in which alone the object that materialism starts with exists), and finally even the will from which all those fundamental forces, that manifest themselves, under the guidance of causes, and therefore according to law, are in truth to be explained. To the assertion that thought is a modification of matter we may always, with equal right, oppose the contrary assertion that all matter is merely the modification of the knowing subject, as its idea. Yet the aim and ideal of all natural science is at bottom a consistent materialism. The recognition here of the obvious impossibility of such a system establishes another truth which will appear in the course of our exposition, the truth that all science properly so called, by which I understand systematic knowledge under the guidance of the principle of sufficient reason, can never reach its final goal, nor give a complete and adequate explanation: for it is not concerned with the inmost nature of the world, it cannot get beyond the idea; indeed, it really teaches nothing more than the relation of one idea to another.

Every science must start from two principal data. One of these is always the principle of sufficient reason in some form or another, as organon; the other is its special object as problem. Thus, for example, geometry has space as problem, and the ground of existence in space as organon. Arithmetic has time as problem, and the ground of existence in time as organon. Logic has the combination of concepts as such as problem, and the ground of knowledge as organon. History has the past acts of men treated as a whole as problem, and the law of human motives as organon. Natural science has matter as problem, and the law of causality as organon. Its end and aim is therefore, by the guidance of causality, to refer all possible states of matter to other states, and ultimately to one single state; and again to deduce these states from each other, and ultimately from one single state. Thus two states of matter stand over against each other in natural science as extremes: that state in which matter is furthest from being the immediate object of the subject, and that state in which it is most completely such an immediate object, *i.e.*, the most dead and crude matter, the primary element, as the one extreme, and the human organism as the other. Natural science as chemistry seeks for the first, as physiology for the second. But as yet neither extreme has been reached, and it is only in the intermediate ground that something has been won. The prospect is indeed somewhat hopeless. The chemists, under the presupposition that the qualitative division of matter is not, like quantitative division, an endless process, are always trying to decrease the number of the elements, of which there are still about sixty; and if they were to succeed in reducing them to two, they would still try to find the common root of these. For, on the one hand, the law of homogeneity leads to the assumption of a primary chemical state of matter, which alone belongs to matter as such, and precedes all others which are not essentially matter as such, but merely contingent forms and qualities. On the other hand, we cannot understand how this one state could ever experience a chemical change, if there did not exist a second state to affect it. Thus the same difficulty appears in chemistry which Epicurus met with in mechanics. For he had to show how the first atom departed from the original direction of its motion. Indeed this contradiction, which develops entirely of itself and can neither be escaped nor solved, might quite properly be set up as a chemical *antinomy*. Thus an antinomy appears in the one extreme of natural science, and a corresponding one will appear in the other. There is just as little hope of reaching this opposite extreme of natural

science, for we see ever more clearly that what is chemical can never be referred to what is mechanical, nor what is organic to what is chemical or electrical. Those who in our own day are entering anew on this old, misleading path, will soon slink back silent and ashamed, as all their predecessors have done before them. We shall consider this more fully in the second book. Natural science encounters the difficulties which we have cursorily mentioned, in its own province. Regarded as philosophy, it would further be materialism; but this, as we have seen, even at its birth, has death in its heart, because it ignores the subject and the forms of knowledge, which are presupposed, just as much in the case of the crudest matter, from which it desires to start, as in that of the organism, at which it desires to arrive. For, "no object without a subject," is the principle which renders all materialism for ever impossible. Suns and planets without an eye that sees them, and an understanding that knows them, may indeed be spoken of in words, but for the idea, these words are absolutely meaningless. On the other hand, the law of causality and the treatment and investigation of nature which is based upon it, lead us necessarily to the conclusion that, in time, each more highly organised state of matter has succeeded a cruder state: so that the lower animals existed before men, fishes before land animals, plants before fishes, and the unorganised before all that is organised; that, consequently, the original mass had to pass through a long series of changes before the first eye could be opened. And yet, the existence of this whole world remains ever dependent upon the first eye that opened, even if it were that of an insect. For such an eye is a necessary condition of the possibility of knowledge, and the whole world exists only in and for knowledge, and without it is not even thinkable. The world is entirely idea, and as such demands the knowing subject as the supporter of its existence. This long course of time itself, filled with innumerable changes, through which matter rose from form to form till at last the first percipient creature appeared, — this whole time itself is only thinkable in the identity of a consciousness whose succession of ideas, whose form of knowing it is, and apart from which, it loses all meaning and is nothing at all. Thus we see, on the one hand, the existence of the whole world necessarily dependent upon the first conscious being, however undeveloped it may be; on the other hand, this conscious being just as necessarily entirely dependent upon a long chain of causes and effects which have preceded it, and in which it itself appears as a small link. These two

contradictory points of view, to each of which we are led with the same necessity, we might again call an *antinomy* in our faculty of knowledge, and set it up as the counterpart of that which we found in the first extreme of natural science. The fourfold antinomy of Kant will be shown, in the criticism of his philosophy appended to this volume, to be a groundless delusion. But the necessary contradiction which at last presents itself to us here, finds its solution in the fact that, to use Kant's phraseology, time, space, and causality do not belong to the thing-in-itself, but only to its phenomena, of which they are the form; which in my language means this: The objective world, the world as idea, is not the only side of the world, but merely its outward side; and it has an entirely different side — the side of its inmost nature — its kernel — the thing-in-itself. This we shall consider in the second book, calling it after the most immediate of its objective manifestations — will. But the world as idea, with which alone we are here concerned, only appears with the opening of the first eye. Without this medium of knowledge it cannot be, and therefore it was not before it. But without that eye, that is to say, outside of knowledge, there was also no before, no time. Thus time has no beginning, but all beginning is in time. Since, however, it is the most universal form of the knowable, in which all phenomena are united together through causality, time, with its infinity of past and future, is present in the beginning of knowledge. The phenomenon which fills the first present must at once be known as causally bound up with and dependent upon a sequence of phenomena which stretches infinitely into the past, and this past itself is just as truly conditioned by this first present, as conversely the present is by the past. Accordingly the past out of which the first present arises, is, like it, dependent upon the knowing subject, without which it is nothing. It necessarily happens, however, that this first present does not manifest itself as the first, that is, as having no past for its parent, but as being the beginning of time. It manifests itself rather as the consequence of the past, according to the principle of existence in time. In the same way, the phenomena which fill this first present appear as the effects of earlier phenomena which filled the past, in accordance with the law of causality. Those who like mythological interpretations may take the birth of Kronos (χρονος), the youngest of the Titans, as a symbol of the moment here referred to at which time appears, though, indeed it has no beginning; for with him, since he ate his father, the crude productions of

heaven and earth cease, and the races of gods and men appear upon the scene.

This explanation at which we have arrived by following the most consistent of the philosophical systems which start from the object, materialism, has brought out clearly the inseparable and reciprocal dependence of subject and object, and at the same time the inevitable antithesis between them. And this knowledge leads us to seek for the inner nature of the world, the thing-in-itself, not in either of the two elements of the idea, but in something quite distinct from it, and which is not encumbered with such a fundamental and insoluble antithesis.

Opposed to the system we have explained, which starts from the object in order to derive the subject from it, is the system which starts from the subject and tries to derive the object from it. The first of these has been of frequent and common occurrence throughout the history of philosophy, but of the second we find only one example, and that a very recent one; the "philosophy of appearance" of J. G. Fichte. In this respect, therefore, it must be considered; little real worth or inner meaning as the doctrine itself had. It was indeed for the most part merely a delusion, but it was delivered with an air of the deepest earnestness, with sustained loftiness of tone and zealous ardour, and was defended with eloquent polemic against weak opponents, so that it was able to present a brilliant exterior and seemed to be something. But the genuine earnestness which keeps truth always steadfastly before it as its goal, and is unaffected by any external influences, was entirely wanting to Fichte, as it is to all philosophers who, like him, concern themselves with questions of the day. In his case, indeed, it could not have been otherwise. A man becomes a philosopher by reason of a certain perplexity, from which he seeks to free himself. This is Plato's θαυμαξειν, which he calls a μαλα φιλοσοφικον παθος. But what distinguishes the false philosopher from the true is this: the perplexity of the latter arises from the contemplation of the world itself, while that of the former results from some book, some system of philosophy which is before him. Now Fichte belongs to the class of the false philosophers. He was made a philosopher by Kant's doctrine of the thing-in-itself, and if it had not been for this he would probably have pursued entirely different ends, with far better results, for he certainly possessed remarkable rhetorical talent. If he had only penetrated somewhat deeply into the meaning of the book that made him a philosopher, "The Critique of Pure Reason," he

would have understood that its principal teaching about mind is this. The principle of sufficient reason is not, as all scholastic philosophy maintains, a *veritas aeterna* — that is to say, it does not possess an unconditioned validity before, outside of, and above the world. It is relative and conditioned, and valid only in the sphere of phenomena, and thus it may appear as the necessary nexus of space and time, or as the law of causality, or as the law of the ground of knowledge. The inner nature of the world, the thing-in-itself can never be found by the guidance of this principle, for all that it leads to will be found to be dependent and relative and merely phenomenal, not the thing-in-itself. Further, it does not concern the subject, but is only the form of objects, which are therefore not things-in-themselves. The subject must exist along with the object, and the object along with the subject, so that it is impossible that subject and object can stand to each other in a relation of reason and consequent. But Fichte did not take up the smallest fragment of all this. All that interested him about the matter was that the system started from the subject. Now Kant had chosen this procedure in order to show the fallacy of the prevalent systems, which started from the object, and through which the object had come, to be regarded as a thing-in-itself. Fichte, however, took this departure from the subject for the really important matter, and like all imitators, he imagined that in going further than Kant he was surpassing him. Thus he repeated the fallacy with regard to the subject, which all the previous dogmatism had perpetrated with regard to the object, and which had been the occasion of Kant's "Critique". Fichte then made no material change, and the fundamental fallacy, the assumption of a relation of reason and consequent between object and subject, remained after him as it was before him. The principle of sufficient reason possessed as before an unconditioned validity, and the only difference was that the thing-in-itself was now placed in the subject instead of, as formerly, in the object. The entire relativity of both subject and object, which proves that the thing-in-itself, or the inner nature of the world, is not to be sought in them at all, but outside of them, and outside everything else that exists merely relatively, still remained unknown. Just as if Kant had never existed, the principle of sufficient reason is to Fichte precisely what it was to all the schoolmen, a *veritas aeterna*. As an eternal fate reigned over the gods of old, so these *aeternæ veritates*, these metaphysical, mathematical and metalogical truths, and in the case of some, the validity of the moral law also, reigned over the God of

the schoolmen. These *veritates* alone were independent of everything, and through their necessity both God and the world existed. According to the principle of sufficient reason, as such a *veritas aeterna*, the *ego* is for Fichte the ground of the world, or of the *non-ego*, the object, which is just its consequent, its creation. He has therefore taken good care to avoid examining further or limiting the principle of sufficient reason. If, however, it is thought I should specify the form of the principle of sufficient reason under the guidance of which Fichte derives the *non-ego* from the *ego*, as a spider spins its web out of itself, I find that it is the principle of sufficient reason of existence in space: for it is only as referred to this that some kind of meaning and sense can be attached to the laboured deductions of the way in which the *ego* produces and fabricates the *non-ego* from itself, which form the content of the most senseless, and consequently the most wearisome book that was ever written. This philosophy of Fichte, otherwise not worth mentioning, is interesting to us only as the tardy expression of the converse of the old materialism. For materialism was the most consistent system starting from the object, as this is the most consistent system starting from the subject. Materialism overlooked the fact that, with the simplest object, it assumed the subject also; and Fichte overlooked the fact that with the subject (whatever he may call it) he assumed the object also, for no subject is thinkable without an object. Besides this he forgot that all *a priori* deduction, indeed all demonstration in general, must rest upon some necessity, and that all necessity is based on the principle of sufficient reason, because to be necessary, and to follow from given grounds are convertible conceptions.[10] But the principle of sufficient reason is just the universal form of the object as such. Thus it is in the object, but is not valid before and outside of it; it first produces the object and makes it appear in conformity with its regulative principle. We see then that the system which starts from the subject contains the same fallacy as the system, explained above, which starts from the object; it begins by assuming what it proposes to deduce, the necessary correlative of its starting-point.

The method of our own system is *toto genere* distinct from these two opposite misconceptions, for we start neither from the object nor from the subject, but from the *idea*, as the first fact of consciousness. Its first essential, fundamental form is the antithesis of subject and object. The form of the object again is the principle of sufficient reason in its various forms. Each of these reigns so absolutely in its own class of ideas that, as we have

seen, when the special form of the principle of sufficient reason which governs any class of ideas is known, the nature of the whole class is known also: for the whole class, as idea, is no more than this form of the principle of sufficient reason itself; so that time itself is nothing but the principle of existence in it, *i.e.*, succession; space is nothing but the principle of existence in it, *i.e.*, position; matter is nothing but causality; the concept (as will appear immediately) is nothing but relation to a ground of knowledge. This thorough and consistent relativity of the world as idea, both according to its universal form (subject and object), and according to the form which is subordinate to this (the principle of sufficient reason) warns us, as we said before, to seek the inner nature of the world in an aspect of it which is *quite different and quite distinct from the idea*; and in the next book we shall find this in a fact which is just as immediate to every living being as the idea.

But we must first consider that class of ideas which belongs to man alone. The matter of these is the concept, and the subjective correlative is reason, just as the subjective correlative of the ideas we have already considered was understanding and sensibility, which are also to be attributed to all the lower animals.[11]

§ 8. As from the direct light of the sun to the borrowed light of the moon, we pass from the immediate idea of perception, which stands by itself and is its own warrant, to reflection, to the abstract, discursive concepts of the reason, which obtain their whole content from knowledge of perception, and in relation to it. As long as we continue simply to perceive, all is clear, firm, and certain. There are neither questions nor doubts nor errors; we desire to go no further, can go no further; we find rest in perceiving, and satisfaction in the present. Perception suffices for itself, and therefore what springs purely from it, and remains true to it, for example, a genuine work of art, can never be false, nor can it be discredited through the lapse of time, for it does not present an opinion but the thing itself. But with abstract knowledge, with reason, doubt and error appear in the theoretical, care and sorrow in the practical. In the idea of perception, illusion may at moments take the place of the real; but in the sphere of abstract thought, error may reign for a thousand years, impose its yoke upon whole nations, extend to the noblest impulses of humanity, and, by the help of its slaves and its dupes, may chain and fetter those whom it cannot deceive. It is the enemy against which the wisest men of all times have waged unequal war, and

only what they have won from it has become the possession of mankind. Therefore it is well to draw attention to it at once, as we already tread the ground to which its province belongs. It has often been said that we ought to follow truth even although no utility can be seen in it, because it may have indirect utility which may appear when it is least expected; and I would add to this, that we ought to be just as anxious to discover and to root out all error even when no harm is anticipated from it, because its mischief may be very indirect, and may suddenly appear when we do not expect it, for all error has poison at its heart. If it is mind, if it is knowledge, that makes man the lord of creation, there can be no such thing as harmless error, still less venerable and holy error. And for the consolation of those who in any way and at any time may have devoted strength and life to the noble and hard battle against error, I cannot refrain from adding that, so long as truth is absent, error will have free play, as owls and bats in the night; but sooner would we expect to see the owls and the bats drive back the sun in the eastern heavens, than that any truth which has once been known and distinctly and fully expressed, can ever again be so utterly vanquished and overcome that the old error shall once more reign undisturbed over its wide kingdom. This is the power of truth; its conquest is slow and laborious, but if once the victory be gained it can never be wrested back again.

Besides the ideas we have as yet considered, which, according to their construction, could be referred to time, space, and matter, if we consider them with reference to the object, or to pure sensibility and understanding (*i.e.*, knowledge of causality), if we consider them with reference to the subject, another faculty of knowledge has appeared in man alone of all earthly creatures, an entirely new consciousness, which, with very appropriate and significant exactness, is called *reflection*. For it is in fact derived from the knowledge of perception, and is a reflected appearance of it. But it has assumed a nature fundamentally different. The forms of perception do not affect it, and even the principle of sufficient reason which reigns over all objects has an entirely different aspect with regard to it. It is just this new, more highly endowed, consciousness, this abstract reflex of all that belongs to perception in that conception of the reason which has nothing to do with perception, that gives to man that thoughtfulness which distinguishes his consciousness so entirely from that of the lower animals, and through which his whole behaviour upon earth is so different from that

of his irrational fellow-creatures. He far surpasses them in power and also in suffering. They live in the present alone, he lives also in the future and the past. They satisfy the needs of the moment, he provides by the most ingenious preparations for the future, yea for days that he shall never see. They are entirely dependent on the impression of the moment, on the effect of the perceptible motive; he is determined by abstract conceptions independent of the present. Therefore he follows predetermined plans, he acts from maxims, without reference to his surroundings or the accidental impression of the moment. Thus, for example, he can make with composure deliberate preparations for his own death, he can dissemble past finding out, and can carry his secret with him to the grave; lastly, he has an actual choice between several motives; for only in the abstract can such motives, present together in consciousness, afford the knowledge with regard to themselves, that the one excludes the other, and can thus measure themselves against each other with reference to their power over the will. The motive that overcomes, in that it decides the question at issue, is the deliberate determinant of the will, and is a sure indication of its character. The brute, on the other hand, is determined by the present impression; only the fear of present compulsion can constrain its desires, until at last this fear has become custom, and as such continues to determine it; this is called training. The brute feels and perceives; man, in addition to this, *thinks* and *knows*: both *will*. The brute expresses its feelings and dispositions by gestures and sounds; man communicates his thought to others, or, if he wishes, he conceals it, by means of speech. Speech is the first production, and also the necessary organ of his reason. Therefore in Greek and Italian, speech and reason are expressed by the same word; ὁ λογος, *il discorso*. *Vernunft* is derived from *vernehmen*, which is not a synonym for the verb to hear, but signifies the consciousness of the meaning of thoughts communicated in words. It is by the help of language alone that reason accomplishes its most important achievements, — the united action of several individuals, the planned co-operation of many thousands, civilisation, the state; also science, the storing up of experience, the uniting of common properties in one concept, the communication of truth, the spread of error, thoughts and poems, dogmas and superstitions. The brute first knows death when it dies, but man draws consciously nearer to it every hour that he lives; and this makes life at times a questionable good even to him who has not recognised this character of constant annihilation in the

whole of life. Principally on this account man has philosophies and religions, though it is uncertain whether the qualities we admire most in his conduct, voluntary rectitude and nobility of feeling, were ever the fruit of either of them. As results which certainly belong only to them, and as productions of reason in this sphere, we may refer to the marvellous and monstrous opinions of philosophers of various schools, and the extraordinary and sometimes cruel customs of the priests of different religions.

It is the universal opinion of all times and of all nations that these manifold and far-reaching achievements spring from a common principle, from that peculiar intellectual power which belongs distinctively to man and which has been called reason, ὁ λογος, το λογιστικον, το λογιμον, *ratio*. Besides this, no one finds any difficulty in recognising the manifestations of this faculty, and in saying what is rational and what is irrational, where reason appears as distinguished from the other faculties and qualities of man, or lastly, in pointing out what, on account of the want of reason, we must never expect even from the most sensible brute. The philosophers of all ages may be said to be on the whole at one about this general knowledge of reason, and they have also given prominence to several very important manifestations of it; such as, the control of the emotions and passions, the capacity for drawing conclusions and formulating general principles, even such as are true prior to all experience, and so forth. Still all their explanations of the peculiar nature of reason are wavering, not clearly defined, discursive, without unity and concentration; now laying stress on one manifestation, now on another, and therefore often at variance with each other. Besides this, many start from the opposition between reason and revelation, a distinction which is unknown to philosophy, and which only increases confusion. It is very remarkable that up till now no philosopher has referred these manifold expressions of reason to one simple function which would be recognised in them all, from which they would all be explained, and which would therefore constitute the real inner nature of reason. It is true that the excellent Locke in the "Essay on the Human Understanding" (Book II., ch. xi., §§ 10 and 11), very rightly refers to general concepts as the characteristic which distinguishes man from the brutes, and Leibnitz quotes this with full approval in the "Nouveaux Essais sur l'Entendement Humaine" (Book II., ch. xi., §§ 10 and 11.) But when Locke (in Book IV., ch. xvii., §§ 2 and 3) comes to the special explanation

of reason he entirely loses sight of this simple, primary characteristic, and he also falls into a wavering, undetermined, incomplete account of mangled and derivative manifestations of it. Leibnitz also, in the corresponding part of his work, behaves in a similar manner, only with more confusion and indistinctness. In the Appendix, I have fully considered how Kant confused and falsified the conception of the nature of reason. But whoever will take the trouble to go through in this reference the mass of philosophical writing which has appeared since Kant, will find out, that just as the faults of princes must be expiated by whole nations, the errors of great minds extend their influence over whole generations, and even over centuries; they grow and propagate themselves, and finally degenerate into monstrosities. All this arises from the fact that, as Berkeley says, "Few men think; yet all will have opinions."

The understanding has only one function — immediate knowledge of the relation of cause and effect. Yet the perception of the real world, and all common sense, sagacity, and inventiveness, however multifarious their applications may be, are quite clearly seen to be nothing more than manifestations of that one function. So also the reason has one function; and from it all the manifestations of reason we have mentioned, which distinguish the life of man from that of the brutes, may easily be explained. The application or the non-application of this function is all that is meant by what men have everywhere and always called rational and irrational.[12]

§ 9. Concepts form a distinct class of ideas, existing only in the mind of man, and entirely different from the ideas of perception which we have considered up till now. We can therefore never attain to a sensuous and, properly speaking, evident knowledge of their nature, but only to a knowledge which is abstract and discursive. It would, therefore, be absurd to demand that they should be verified in experience, if by experience is meant the real external world, which consists of ideas of perception, or that they should be brought before the eyes or the imagination like objects of perception. They can only be thought, not perceived, and only the effects which men accomplish through them are properly objects of experience. Such effects are language, preconceived and planned action and science, and all that results from these. Speech, as an object of outer experience, is obviously nothing more than a very complete telegraph, which communicates arbitrary signs with the greatest rapidity and the finest distinctions of difference. But what do these signs mean? How are they

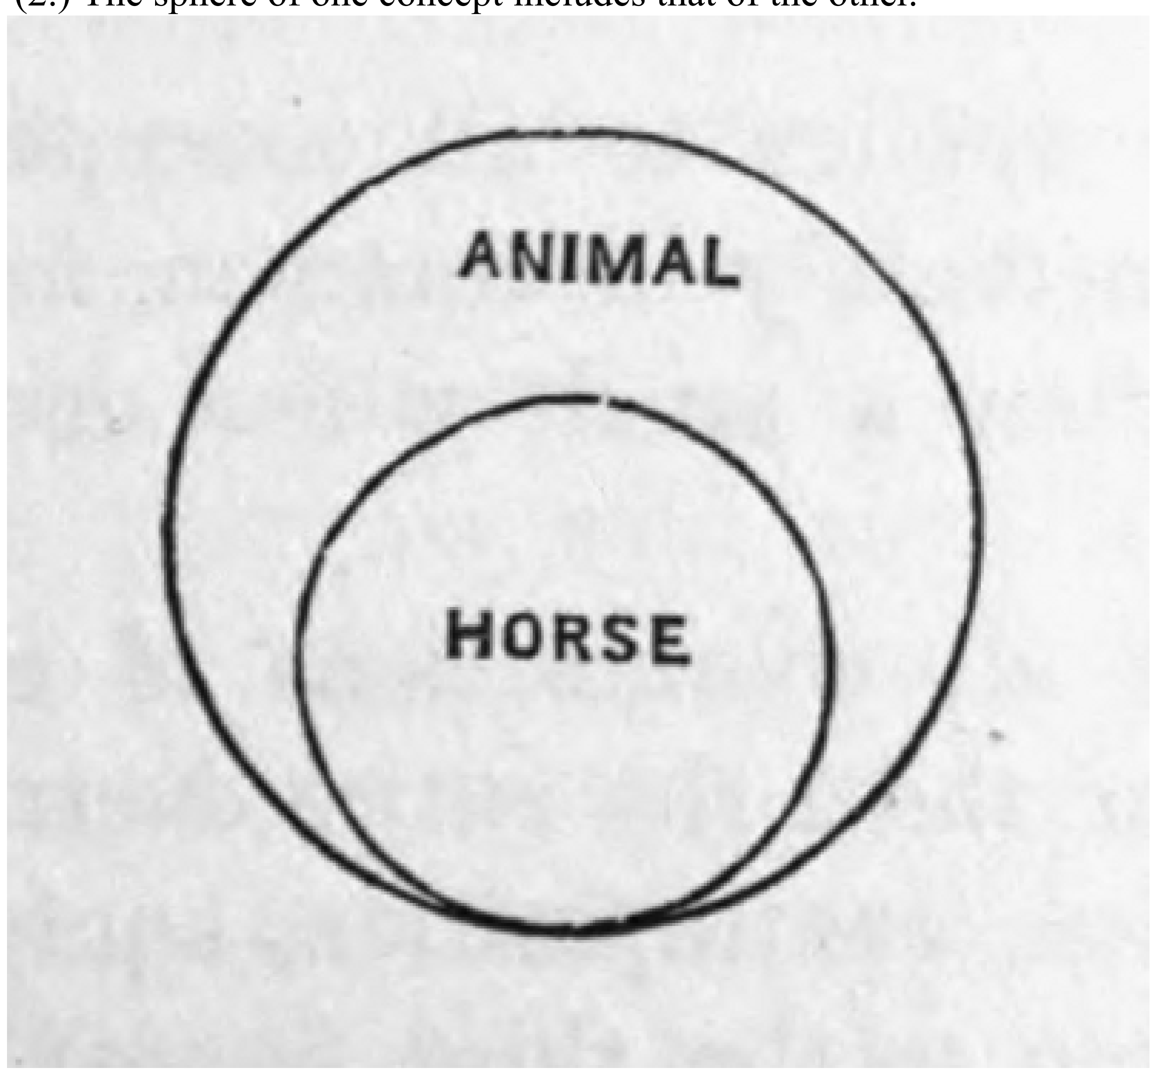
interpreted? When some one speaks, do we at once translate his words into pictures of the fancy, which instantaneously flash upon us, arrange and link themselves together, and assume form and colour according to the words that are poured forth, and their grammatical inflections? What a tumult there would be in our brains while we listened to a speech, or to the reading of a book? But what actually happens is not this at all. The meaning of a speech is, as a rule, immediately grasped, accurately and distinctly taken in, without the imagination being brought into play. It is reason which speaks to reason, keeping within its own province. It communicates and receives abstract conceptions, ideas that cannot be presented in perceptions, which are framed once for all, and are relatively few in number, but which yet encompass, contain, and represent all the innumerable objects of the actual world. This itself is sufficient to prove that the lower animals can never learn to speak or comprehend, although they have the organs of speech and ideas of perception in common with us. But because words represent this perfectly distinct class of ideas, whose subjective correlative is reason, they are without sense and meaning for the brutes. Thus language, like every other manifestation which we ascribe to reason, and like everything which distinguishes man from the brutes, is to be explained from this as its one simple source — conceptions, abstract ideas which cannot be presented in perception, but are general, and have no individual existence in space and time. Only in single cases do we pass from the conception to the perception, do we construct images as *representatives of concepts* in perception, to which, however, they are never adequate. These cases are fully discussed in the essay on the principle of sufficient reason, § 28, and therefore I shall not repeat my explanation here. It may be compared, however, with what is said by Hume in the twelfth of his "Philosophical Essays," p. 244, and by Herder in the "Metacritik," pt. i. p. 274 (an otherwise worthless book). The Platonic idea, the possibility of which depends upon the union of imagination and reason, is the principal subject of the third book of this work.

Although concepts are fundamentally different from ideas of perception, they stand in a necessary relation to them, without which they would be nothing. This relation therefore constitutes the whole nature and existence of concepts. Reflection is the necessary copy or repetition of the originally presented world of perception, but it is a special kind of copy in an entirely different material. Thus concepts may quite properly be called ideas of ideas. The principle of sufficient reason has here also a special form. Now

we have seen that the form under which the principle of sufficient reason appears in a class of ideas always constitutes and exhausts the whole nature of the class, so far as it consists of ideas, so that time is throughout succession, and nothing more; space is throughout position, and nothing more; matter is throughout causation, and nothing more. In the same way the whole nature of concepts, or the class of abstract ideas, consists simply in the relation which the principle of sufficient reason expresses in them; and as this is the relation to the ground of knowledge, the whole nature of the abstract idea is simply and solely its relation to another idea, which is its ground of knowledge. This, indeed, may, in the first instance, be a concept, an abstract idea, and this again may have only a similar abstract ground of knowledge; but the chain of grounds of knowledge does not extend *ad infinitum*; it must end at last in a concept which has its ground in knowledge of perception; for the whole world of reflection rests on the world of perception as its ground of knowledge. Hence the class of abstract ideas is in this respect distinguished from other classes; in the latter the principle of sufficient reason always demands merely a relation to another idea of the *same* class, but in the case of abstract ideas, it at last demands a relation to an idea of *another* class.

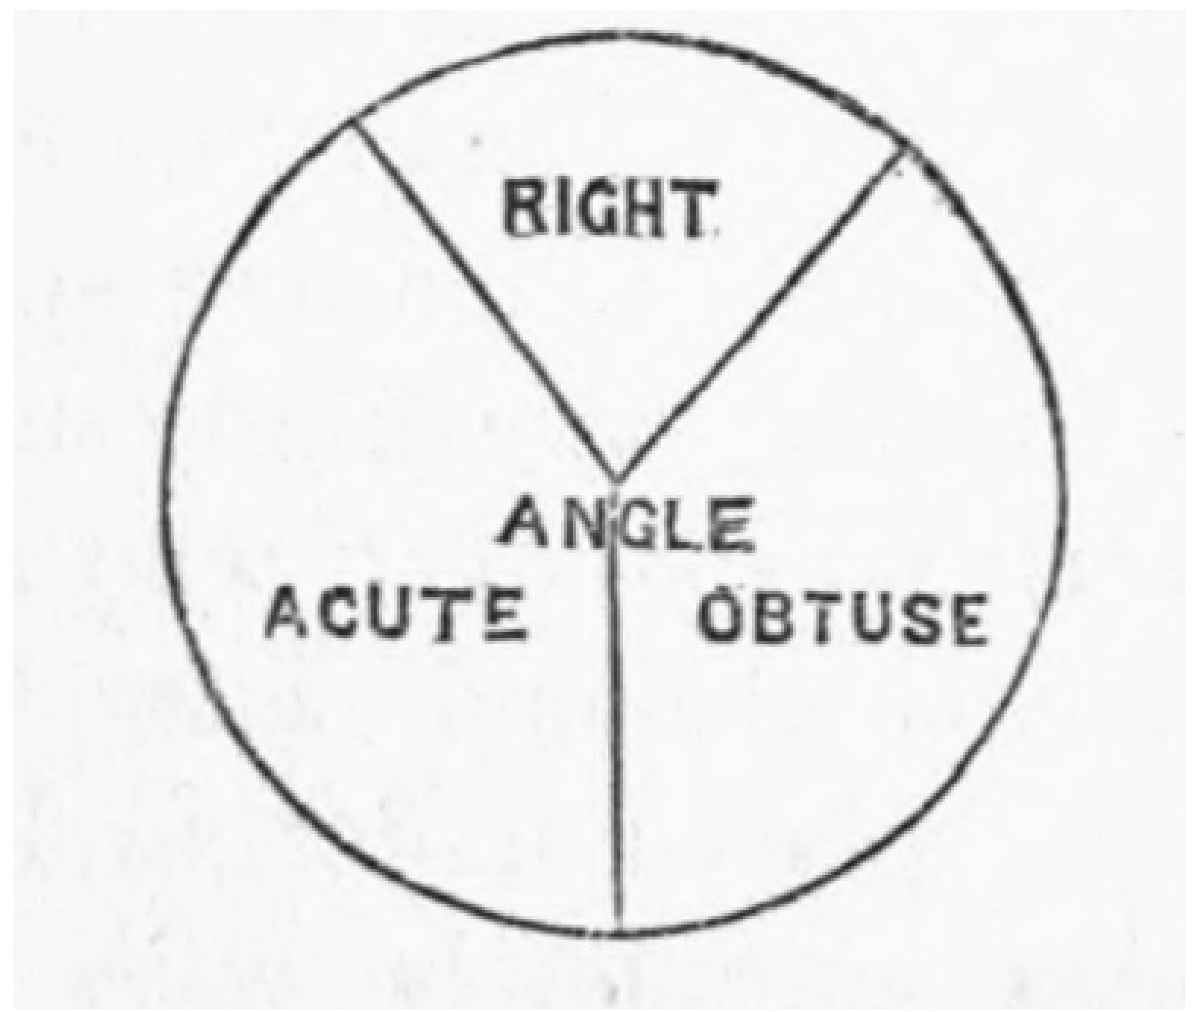
Those concepts which, as has just been pointed out, are not immediately related to the world of perception, but only through the medium of one, or it may be several other concepts, have been called by preference *abstracta*, and those which have their ground immediately in the world of perception have been called *concreta*. But this last name is only loosely applicable to the concepts denoted by it, for they are always merely *abstracta*, and not ideas of perception. These names, which have originated in a very dim consciousness of the distinctions they imply, may yet, with this explanation, be retained. As examples of the first kind of concepts, *i.e.*, *abstracta* in the fullest sense, we may take "relation," "virtue," "investigation," "beginning," and so on. As examples of the second kind, loosely called *concreta*, we may take such concepts as "man," "stone," "horse," &c. If it were not a somewhat too pictorial and therefore absurd simile, we might very appropriately call the latter the ground floor, and the former the upper stories of the building of reflection.[13]

It is not, as is commonly supposed, an essential characteristic of a concept that it should contain much under it, that is to say, that many ideas of perception, or it may be other abstract ideas, should stand to it in the



relation of its ground of knowledge, *i.e.*, be thought through it. This is merely a derived and secondary characteristic, and, as a matter of fact, does not always exist, though it must always exist potentially. This characteristic arises from the fact that a concept is an idea of an idea, *i.e.*, its whole nature consists in its relation to another idea; but as it is not this idea itself, which is generally an idea of perception and therefore belongs to quite a different class, the latter may have temporal, spacial, and other determinations, and in general many relations which are not thought along with it in the concept. Thus we see that several ideas which are different in unessential particulars may be thought by means of one concept, *i.e.*, may be brought under it. Yet this power of embracing several things is not an essential but merely an accidental characteristic of the concept. There may be concepts through which only one real object is thought, but which are nevertheless abstract and general, by no means capable of presentation individually and as perceptions. Such, for example, is the conception which any one may have of a particular town which he only knows from geography; although only this one town is thought under it, it might yet be applied to several towns differing in certain respects. We see then that a concept is not general because of being abstracted from several objects; but conversely, because generality, that is to say, non-determination of the particular, belongs to the concept as an abstract idea of the reason, different things can be thought by means of the same one.

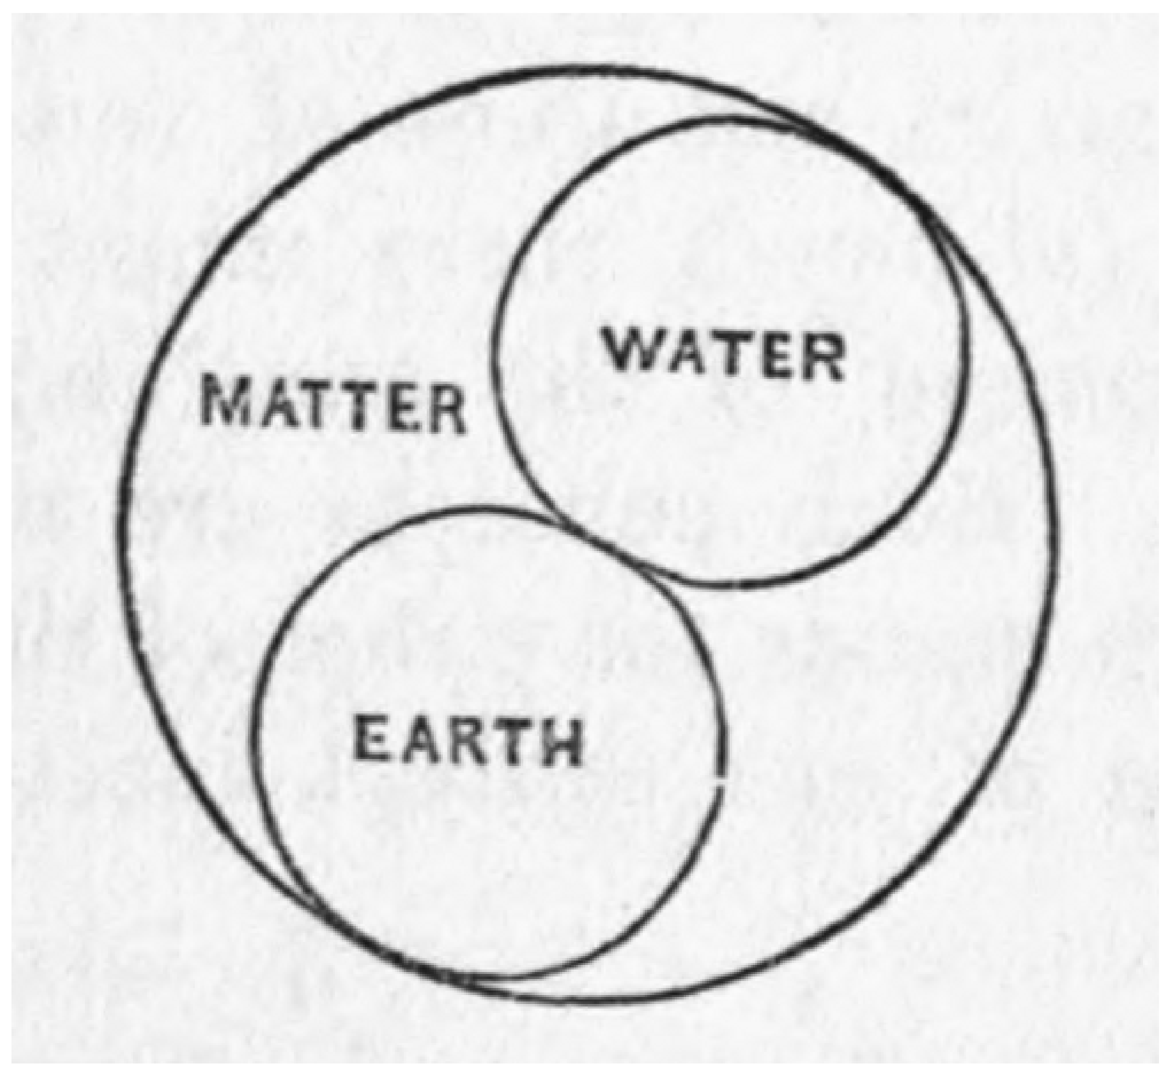
It follows from what has been said that every concept, just because it is abstract and incapable of presentation in perception, and is therefore not a completely determined idea, has what is called extension or sphere, even in the case in which only one real object exists that corresponds to it. Now we always find that the sphere of one concept has something in common with the sphere of other concepts. That is to say, part of what is thought under one concept is the same as what is thought under other concepts; and conversely, part of what is thought under these concepts is the same as what is thought under the first; although, if they are really different concepts, each of them, or at least one of them, contains something which the other does not contain; this is the relation in which every subject stands to its predicate. The recognition of this relation is called judgment. The representation of these spheres by means of figures in space, is an exceedingly happy idea. It first occurred to Gottfried Plouquet, who used squares for the purpose. Lambert, although later than him, used only lines,



which he placed under each other. Euler carried out the idea completely with circles. Upon what this complete analogy between the relations of concepts, and those of figures in space, ultimately rests, I am unable to say. It is, however, a very fortunate circumstance for logic that all the relations of concepts, according to their possibility, *i.e.*, *a priori*, may be made plain in perception by the use of such figures, in the following way: —

(1.) The spheres of two concepts coincide: for example the concept of necessity and the concept of following from given grounds, in the same way the concepts of *Ruminantia* and *Bisulca* (ruminating and cloven-hoofed animals), also those of vertebrate and red-blooded animals (although there might be some doubt about this on account of the annelida): they are convertible concepts. Such concepts are represented by a single circle which stands for either of them.

(2.) The sphere of one concept includes that of the other.



(3.) A sphere includes two or more spheres which exclude each other and fill it.

(4.) Two spheres include each a part of the other.

(5.) Two spheres lie in a third, but do not fill it.

This last case applies to all concepts whose spheres have nothing immediately in common, for there is always a third sphere, often a much wider one, which includes both.

To these cases all combinations of concepts may be referred, and from them the entire doctrine of the judgment, its conversion, contraposition, equipollence, disjunction (this according to the third figure) may be deduced. From these also may be derived the properties of the judgment, upon which Kant based his pretended categories of the understanding, with the exception however of the hypothetical form, which is not a combination of concepts, but of judgments. A full account is given in the Appendix of "Modality," and indeed of every property of judgments on which the categories are founded.

With regard to the possible combinations of concepts which we have given, it has only further to be remarked that they may also be combined

with each other in many ways. For example, the fourth figure with the second. Only if one sphere, which partly or wholly contains another, is itself contained in a third sphere, do these together exemplify the syllogism in the first figure, *i.e.*, that combination of judgments, by means of which it is known that a concept which is partly or wholly contained in another concept, is also contained in a third concept, which again contains the first: and also, conversely, the negation; the pictorial representation of which can, of course, only be two connected spheres which do not lie within a third sphere. If many spheres are brought together in this way we get a long train of syllogisms. This schematism of concepts, which has already been fairly well explained in more than one textbook, may be used as the foundation of the doctrine of the judgment, and indeed of the whole syllogistic theory, and in this way the treatment of both becomes very easy and simple. Because, through it, all syllogistic rules may be seen in their origin, and may be deduced and explained. It is not necessary, however, to load the memory with these rules, as logic is never of practical use, but has only a theoretical interest for philosophy. For although it may be said that logic is related to rational thinking as thorough-bass is to music, or less exactly, as ethics is to virtue, or æsthetics to art; we must yet remember that no one ever became an artist by the study of æsthetics; that a noble character was never formed by the study of ethics; that long before Rameau, men composed correctly and beautifully, and that we do not need to know thorough-bass in order to detect discords: and just as little do we need to know logic in order to avoid being misled by fallacies. Yet it must be conceded that thorough-bass is of the greatest use in the practice of musical composition, although it may not be necessary for the understanding of it; and indeed æsthetics and even ethics, though in a much less degree, and for the most part negatively, may be of some use in practice, so that we cannot deny them all practical worth, but of logic even this much cannot be conceded. It is nothing more than the knowledge in the abstract of what every one knows in the concrete. Therefore we call in the aid of logical rules, just as little to enable us to construct a correct argument as to prevent us from consenting to a false one, and the most learned logician lays aside the rules of logic altogether in his actual thought. This may be explained in the following way. Every science is a system of general and therefore abstract truths, laws, and rules with reference to a special class of objects. The individual case coming under these laws is determined in accordance with this general knowledge, which

is valid once for all; because such application of the general principle is far easier than the exhaustive investigation of the particular case; for the general abstract knowledge which has once been obtained is always more within our reach than the empirical investigation of the particular case. With logic, however, it is just the other way. It is the general knowledge of the mode of procedure of the reason expressed in the form of rules. It is reached by the introspection of reason, and by abstraction from all content. But this mode of procedure is necessary and essential to reason, so that it will never depart from it if left to itself. It is, therefore, easier and surer to let it proceed itself according to its nature in each particular case, than to present to it the knowledge abstracted from this procedure in the form of a foreign and externally given law. It is easier, because, while in the case of all other sciences, the general rule is more within our reach than the investigation of the particular case taken by itself; with the use of reason, on the contrary, its necessary procedure in a given case is always more within our reach than the general rule abstracted from it; for that which thinks in us is reason itself. It is surer, because a mistake may more easily occur in such abstract knowledge, or in its application, than that a process of reason should take place which would run contrary to its essence and nature. Hence arises the remarkable fact, that while in other sciences the particular case is always proved by the rule, in logic, on the contrary, the rule must always be proved from the particular case; and even the most practised logician, if he remark that in some particular case he concludes otherwise than the rule prescribes, will always expect to find a mistake in the rule rather than in his own conclusion. To desire to make practical use of logic means, therefore, to desire to derive with unspeakable trouble, from general rules, that which is immediately known with the greatest certainty in the particular case. It is just as if a man were to consult mechanics as to the motion of his body, and physiology as to his digestion; and whoever has learnt logic for practical purposes is like him who would teach a beaver to make its own dam. Logic is, therefore, without practical utility; but it must nevertheless be retained, because it has philosophical interest as the special knowledge of the organisation and action of reason. It is rightly regarded as a definite, self-subsisting, self-contained, complete, and thoroughly safe discipline; to be treated scientifically for itself alone and independently of everything else, and therefore to be studied at the universities. But it has its real value, in relation to philosophy as a whole, in the inquiry into the nature of

knowledge, and indeed of rational and abstract knowledge. Therefore the exposition of logic should not have so much the form of a practical science, should not contain merely naked arbitrary rules for the correct formation of the judgment, the syllogism, &c., but should rather be directed to the knowledge of the nature of reason and the concept, and to the detailed investigation of the principle of sufficient reason of knowing. For logic is only a paraphrase of this principle, and, more exactly, only of that exemplification of it in which the ground that gives truth to the judgment is neither empirical nor metaphysical, but logical or metalogical. Besides the principle of sufficient reason of knowing, it is necessary to take account of the three remaining fundamental laws of thought, or judgments of metalogical truth, so nearly related to it; and out of these the whole science of reason grows. The nature of thought proper, that is to say, of the judgment and the syllogism, must be exhibited in the combination of the spheres of concepts, according to the analogy of the special schema, in the way shown above; and from all this the rules of the judgment and the syllogism are to be deduced by construction. The only practical use we can make of logic is in a debate, when we can convict our antagonist of his intentional fallacies, rather than of his actual mistakes, by giving them their technical names. By thus throwing into the background the practical aim of logic, and bringing out its connection with the whole scheme of philosophy as one of its chapters, we do not think that we shall make the study of it less prevalent than it is just now. For at the present day every one who does not wish to remain uncultured, and to be numbered with the ignorant and incompetent multitude, must study speculative philosophy. For the nineteenth century is a philosophical age, though by this we do not mean either that it has philosophy, or that philosophy governs it, but rather that it is ripe for philosophy, and, therefore, stands in need of it. This is a sign of a high degree of civilisation, and indeed, is a definite stage in the culture of the ages.[14]

Though logic is of so little practical use, it cannot be denied that it was invented for practical purposes. It appears to me to have originated in the following way: — As the love of debating developed among the Eleatics, the Megarics, and the Sophists, and by degrees became almost a passion, the confusion in which nearly every debate ended must have made them feel the necessity of a method of procedure as a guide; and for this a scientific dialectic had to be sought. The first thing which would have to be

observed would be that both the disputing parties should always be agreed on some one proposition, to which the disputed points might be referred. The beginning of the methodical procedure consisted in this, that the propositions admitted on both sides were formally stated to be so, and placed at the head of the inquiry. But these propositions were at first concerned only with the material of the inquiry. It was soon observed that in the process of going back to the truth admitted on both sides, and of deducing their assertions from it, each party followed certain forms and laws about which, without any express agreement, there was no difference of opinion. And from this it became evident that these must constitute the peculiar and natural procedure of reason itself, the form of investigation. Although this was not exposed to any doubt or difference of opinion, some pedantically systematic philosopher hit upon the idea that it would look well, and be the completion of the method of dialectic, if this formal part of all discussion, this regular procedure of reason itself, were to be expressed in abstract propositions, just like the substantial propositions admitted on both sides, and placed at the beginning of every investigation, as the fixed canon of debate to which reference and appeal must always be made. In this way what had formerly been followed only by tacit agreement, and instinctively, would be consciously recognised and formally expressed. By degrees, more or less perfect expressions were found for the fundamental principles of logic, such as the principles of contradiction, sufficient reason, excluded middle, the *dictum de omni et nullo*, as well as the special rules of the syllogism, as for example, *ex meris particularibus aut negativis nihil sequitur, a rationato ad rationem non valet consequentia*, and so on. That all this was only brought about slowly, and with great pains, and up till the time of Aristotle remained very incomplete, is evident from the awkward and tedious way in which logical truths are brought out in many of the Platonic dialogues, and still more from what Sextus Empiricus tells us of the controversies of the Megarics, about the easiest and simplest logical rules, and the laborious way in which they were brought into a definite form (Sext. Emp. adv. Math. l. 8, p. 112). But Aristotle collected, arranged, and corrected all that had been discovered before his time, and brought it to an incomparably greater state of perfection. If we thus observe how the course of Greek culture had prepared the way for, and led up to the work of Aristotle, we shall be little inclined to believe the assertion of the Persian author, quoted by Sir William Jones with much approval, that Kallisthenes

found a complete system of logic among the Indians, and sent it to his uncle Aristotle (Asiatic Researches, vol. iv. p. 163). It is easy to understand that in the dreary middle ages the Aristotelian logic would be very acceptable to the controversial spirit of the schoolmen, which, in the absence of all real knowledge, spent its energy upon mere formulas and words, and that it would be eagerly adopted even in its mutilated Arabian form, and presently established as the centre of all knowledge. Though its authority has since declined, yet up to our own time logic has retained the credit of a self-contained, practical, and highly important science. Indeed, in our own day, the Kantian philosophy, the foundation-stone of which is taken from logic, has excited a new interest in it; which, in this respect, at any rate, that is, as the means of the knowledge of the nature of reason, it deserves.

Correct and accurate conclusions may be arrived at if we carefully observe the relation of the spheres of concepts, and only conclude that one sphere is contained in a third sphere, when we have clearly seen that this first sphere is contained in a second, which in its turn is contained in the third. On the other hand, the art of sophistry lies in casting only a superficial glance at the relations of the spheres of the concepts, and then manipulating these relations to suit our purposes, generally in the following way: — When the sphere of an observed concept lies partly within that of another concept, and partly within a third altogether different sphere, we treat it as if it lay entirely within the one or the other, as may suit our purpose. For example, in speaking of passion, we may subsume it under the concept of the greatest force, the mightiest agency in the world, or under the concept of the irrational, and this again under the concept of impotency or weakness. We may then repeat the process, and start anew with each concept to which the argument leads us. A concept has almost always several others, which partially come under it, and each of these contains part of the sphere of the first, but also includes in its own sphere something more, which is not in the first. But we draw attention only to that one of these latter concepts, under which we wish to subsume the first, and let the others remain unobserved, or keep them concealed. On the possession of this skill depends the whole art of sophistry and all finer fallacies; for logical fallacies such as *mentiens*, *velatus*, *cornatus*, &c., are clearly too clumsy for actual use. I am not aware that hitherto any one has traced the nature of all sophistry and persuasion back to this last possible ground of its existence, and referred it to the peculiar character of concepts, *i.e.*, to the procedure of reason itself.

Therefore, as my exposition has led me to it, though it is very easily understood, I will illustrate it in the following table by means of a schema. This table is intended to show how the spheres of concepts overlap each other at many points, and so leave room for a passage from each concept to whichever one we please of several other concepts. I hope, however, that no one will be led by this table to attach more importance to this little explanation, which I have merely given in passing, than ought to belong to it, from the nature of the subject. I have chosen as an illustration the concept of travelling. Its sphere partially includes four others, to any of which the sophist may pass at will; these again partly include other spheres, several of them two or more at once, and through these the sophist takes whichever way he chooses, always as if it were the only way, till at last he reaches, in good or evil, whatever end he may have in view. In passing from one sphere to another, it is only necessary always to follow the direction from the centre (the given chief concept) to the circumference, and never to reverse this process. Such a piece of sophistry may be either an unbroken speech, or it may assume the strict syllogistic form, according to what is the weak side of the hearer. Most scientific arguments, and especially philosophical demonstrations, are at bottom not much more than this, for how else would it be possible, that so much, in different ages, has not only been falsely apprehended (for error itself has a different source), but demonstrated and proved, and has yet afterwards been found to be fundamentally wrong, for example, the Leibnitz-Wolfian Philosophy, Ptolemaic Astronomy, Stahl's Chemistry, Newton's Theory of Colours, &c. &c.[15]

§ 10. Through all this, the question presses ever more upon us, how *certainty* is to be attained, how *judgments are to be established*, what constitutes *rational knowledge*, (*wissen*), and *science*, which we rank with language and deliberate action as the third great benefit conferred by reason.

Reason is feminine in nature; it can only give after it has received. Of itself it has nothing but the empty forms of its operation. There is no absolutely pure rational knowledge except the four principles to which I have attributed metalogical truth; the principles of identity, contradiction, excluded middle, and sufficient reason of knowledge. For even the rest of logic is not absolutely pure rational knowledge. It presupposes the relations and the combinations of the spheres of concepts. But concepts in general only exist after experience of ideas of perception, and as their whole nature

consists in their relation to these, it is clear that they presuppose them. No special content, however, is presupposed, but merely the existence of a content generally, and so logic as a whole may fairly pass for pure rational science. In all other sciences reason has received its content from ideas of perception; in mathematics from the relations of space and time, presented in intuition or perception prior to all experience; in pure natural science, that is, in what we know of the course of nature prior to any experience, the content of the science proceeds from the pure understanding, *i.e.*, from the *a priori* knowledge of the law of causality and its connection with those pure intuitions or perceptions of space and time. In all other sciences everything that is not derived from the sources we have just referred to belongs to experience. Speaking generally, *to know rationally* (*wissen*) means to have in the power of the mind, and capable of being reproduced at will, such judgments as have their sufficient ground of knowledge in something outside themselves, *i.e.*, are true. Thus only abstract cognition is *rational knowledge* (*wissen*), which is therefore the result of reason, so that we cannot accurately say of the lower animals that they *rationally know* (*wissen*) anything, although they have apprehension of what is presented in perception, and memory of this, and consequently imagination, which is further proved by the circumstance that they dream. We attribute consciousness to them, and therefore although the word (*bewusstsein*) is derived from the verb to know rationally (*wissen*), the conception of consciousness corresponds generally with that of idea of whatever kind it may be. Thus we attribute life to plants, but not consciousness. *Rational knowledge* (*wissen*) is therefore abstract consciousness, the permanent possession in concepts of the reason, of what has become known in another way.

§ 11. In this regard the direct opposite of *rational knowledge* is feeling, and therefore we must insert the explanation of feeling here. The concept which the word feeling denotes has merely a negative content, which is this, that something which is present in consciousness, *is not a concept*, *is not abstract rational knowledge*. Except this, whatever it may be, it comes under the concept of *feeling*. Thus the immeasurably wide sphere of the concept of feeling includes the most different kinds of objects, and no one can ever understand how they come together until he has recognised that they all agree in this negative respect, that they are not *abstract concepts*.

For the most diverse and even antagonistic elements lie quietly side by side in this concept; for example, religious feeling, feeling of sensual pleasure, moral feeling, bodily feeling, as touch, pain, sense of colour, of sounds and their harmonies and discords, feeling of hate, of disgust, of self-satisfaction, of honour, of disgrace, of right, of wrong, sense of truth, æsthetic feeling, feeling of power, weakness, health, friendship, love, &c. &c. There is absolutely nothing in common among them except the negative quality that they are not abstract rational knowledge. But this diversity becomes more striking when the apprehension of space relations presented *a priori* in perception, and also the knowledge of the pure understanding is brought under this concept, and when we say of all knowledge and all truth, of which we are first conscious only intuitively, and have not yet formulated in abstract concepts, we *feel* it. I should like, for the sake of illustration, to give some examples of this taken from recent books, as they are striking proofs of my theory. I remember reading in the introduction to a German translation of Euclid, that we ought to make beginners in geometry draw the figures before proceeding to demonstrate, for in this way they would already feel geometrical truth before the demonstration brought them complete knowledge. In the same way Schleiermacher speaks in his "Critique of Ethics" of logical and mathematical feeling (p. 339), and also of the feeling of the sameness or difference of two formulas (p. 342). Again Tennemann in his "History of Philosophy" (vol. I., p. 361) says, "One *felt* that the fallacies were not right, but could not point out the mistakes." Now, so long as we do not regard this concept "*feeling*" from the right point of view, and do not recognise that one negative characteristic which alone is essential to it, it must constantly give occasion for misunderstanding and controversy, on account of the excessive wideness of its sphere, and its entirely negative and very limited content which is determined in a purely one-sided manner. Since then we have in German the nearly synonymous word *empfindung* (sensation), it would be convenient to make use of it for bodily feeling, as a sub-species. This concept "feeling," which is quite out of proportion to all others, doubtless originated in the following manner. All concepts, and concepts alone, are denoted by words; they exist only for the reason, and proceed from it. With concepts, therefore, we are already at a one-sided point of view; but from such a point of view what is near appears distinct and is set down as positive, what is farther off becomes mixed up and is soon regarded as merely negative. Thus each nation calls all others

foreign: to the Greek all others are barbarians; to the Englishman all that is not England or English is continent or continental; to the believer all others are heretics, or heathens; to the noble all others are *roturiers*; to the student all others are Philistines, and so forth. Now, reason itself, strange as it may seem, is guilty of the same one-sidedness, indeed one might say of the same crude ignorance arising from vanity, for it classes under the one concept, "*feeling*," every modification of consciousness which does not immediately belong to its own mode of apprehension, that is to say, which is *not an abstract concept*. It has had to pay the penalty of this hitherto in misunderstanding and confusion in its own province, because its own procedure had not become clear to it through thorough self-knowledge, for a special faculty of feeling has been set up, and new theories of it are constructed.

§ 12. *Rational knowledge* (*wissen*) is then all abstract knowledge, — that is, the knowledge which is peculiar to the reason as distinguished from the understanding. Its contradictory opposite has just been explained to be the concept "feeling." Now, as reason only reproduces, for knowledge, what has been received in another way, it does not actually extend our knowledge, but only gives it another form. It enables us to know in the abstract and generally, what first became known in sense-perception, in the concrete. But this is much more important than it appears at first sight when so expressed. For it depends entirely upon the fact that knowledge has become rational or abstract knowledge (*wissen*), that it can be safely preserved, that it is communicable and susceptible of certain and wide-reaching application to practice. Knowledge in the form of sense-perception is valid only of the particular case, extends only to what is nearest, and ends with it, for sensibility and understanding can only comprehend one object at a time. Every enduring, arranged, and planned activity must therefore proceed from principles, — that is, from abstract knowledge, and it must be conducted in accordance with them. Thus, for example, the knowledge of the relation of cause and effect arrived at by the understanding, is in itself far completer, deeper and more exhaustive than anything that can be thought about it in the abstract; the understanding alone knows in perception directly and completely the nature of the effect of a lever, of a pulley, or a cog-wheel, the stability of an arch, and so forth. But on account of the peculiarity of the knowledge of perception just referred to, that it only extends to what is immediately present, the mere understanding can never

enable us to construct machines and buildings. Here reason must come in; it must substitute abstract concepts for ideas of perception, and take them as the guide of action; and if they are right, the anticipated result will happen. In the same way we have perfect knowledge in pure perception of the nature and constitution of the parabola, hyperbola, and spiral; but if we are to make trustworthy application of this knowledge to the real, it must first become abstract knowledge, and by this it certainly loses its character of intuition or perception, but on the other hand it gains the certainty and preciseness of abstract knowledge. The differential calculus does not really extend our knowledge of the curve, it contains nothing that was not already in the mere pure perception of the curve; but it alters the kind of knowledge, it changes the intuitive into an abstract knowledge, which is so valuable for application. But here we must refer to another peculiarity of our faculty of knowledge, which could not be observed until the distinction between the knowledge of the senses and understanding and abstract knowledge had been made quite clear. It is this, that relations of space cannot as such be directly translated into abstract knowledge, but only temporal quantities, — that is, numbers, are suitable for this. Numbers alone can be expressed in abstract concepts which accurately correspond to them, not spacial quantities. The concept "thousand" is just as different from the concept "ten," as both these temporal quantities are in perception. We think of a thousand as a distinct multiple of ten, into which we can resolve it at pleasure for perception in time, — that is to say, we can count it. But between the abstract concept of a mile and that of a foot, apart from any concrete perception of either, and without the help of number, there is no accurate distinction corresponding to the quantities themselves. In both we only think of a spacial quantity in general, and if they must be completely distinguished we are compelled either to call in the assistance of intuition or perception in space, which would be a departure from abstract knowledge, or we must think the difference in *numbers*. If then we wish to have abstract knowledge of space-relations we must first translate them into time-relations, — that is, into numbers; therefore only arithmetic, and not geometry, is the universal science of quantity, and geometry must be translated into arithmetic if it is to be communicable, accurately precise and applicable in practice. It is true that a space-relation as such may also be thought in the abstract; for example, "the sine increases as the angle," but if the quantity of this relation is to be given, it requires number for its

expression. This necessity, that if we wish to have abstract knowledge of space-relations (*i.e.*, rational knowledge, not mere intuition or perception), space with its three dimensions must be translated into time which has only one dimension, this necessity it is, which makes mathematics so difficult. This becomes very clear if we compare the perception of curves with their analytical calculation, or the table of logarithms of the trigonometrical functions with the perception of the changing relations of the parts of a triangle, which are expressed by them. What vast mazes of figures, what laborious calculations it would require to express in the abstract what perception here apprehends at a glance completely and with perfect accuracy, namely, how the co-sine diminishes as the sine increases, how the co-sine of one angle is the sine of another, the inverse relation of the increase and decrease of the two angles, and so forth. How time, we might say, must complain, that with its one dimension it should be compelled to express the three dimensions of space! Yet this is necessary if we wish to possess, for application, an expression, in abstract concepts, of space-relations. They could not be translated directly into abstract concepts, but only through the medium of the pure temporal quantity, number, which alone is directly related to abstract knowledge. Yet it is worthy of remark, that as space adapts itself so well to perception, and by means of its three dimensions, even its complicated relations are easily apprehended, while it eludes the grasp of abstract knowledge; time, on the contrary, passes easily into abstract knowledge, but gives very little to perception. Our perceptions of numbers in their proper element, mere time, without the help of space, scarcely extends as far as ten, and beyond that we have only abstract concepts of numbers, no knowledge of them which can be presented in perception. On the other hand, we connect with every numeral, and with all algebraical symbols, accurately defined abstract concepts.

We may further remark here that some minds only find full satisfaction in what is known through perception. What they seek is the reason and consequent of being in space, sensuously expressed; a demonstration after the manner of Euclid, or an arithmetical solution of spacial problems, does not please them. Other minds, on the contrary, seek merely the abstract concepts which are needful for applying and communicating knowledge. They have patience and memory for abstract principles, formulas, demonstrations in long trains of reasoning, and calculations, in which the

symbols represent the most complicated abstractions. The latter seek preciseness, the former sensible perception. The difference is characteristic.

The greatest value of rational or abstract knowledge is that it can be communicated and permanently retained. It is principally on this account that it is so inestimably important for practice. Any one may have a direct perceptive knowledge through the understanding alone, of the causal connection, of the changes and motions of natural bodies, and he may find entire satisfaction in it; but he cannot communicate this knowledge to others until it has been made permanent for thought in concepts. Knowledge of the first kind is even sufficient for practice, if a man puts his knowledge into practice himself, in an action which can be accomplished while the perception is still vivid; but it is not sufficient if the help of others is required, or even if the action is his own but must be carried out at different times, and therefore requires a pre-conceived plan. Thus, for example, a practised billiard-player may have a perfect knowledge of the laws of the impact of elastic bodies upon each other, merely in the understanding, merely for direct perception; and for him it is quite sufficient; but on the other hand it is only the man who has studied the science of mechanics, who has, properly speaking, a rational knowledge of these laws, that is, a knowledge of them in the abstract. Such knowledge of the understanding in perception is sufficient even for the construction of machines, when the inventor of the machine executes the work himself; as we often see in the case of talented workmen, who have no scientific knowledge. But whenever a number of men, and their united action taking place at different times, is required for the completion of a mechanical work, of a machine, or a building, then he who conducts it must have thought out the plan in the abstract, and such co-operative activity is only possible through the assistance of reason. It is, however, remarkable that in the first kind of activity, in which we have supposed that one man alone, in an uninterrupted course of action, accomplishes something, abstract knowledge, the application of reason or reflection, may often be a hindrance to him; for example, in the case of billiard-playing, of fighting, of tuning an instrument, or in the case of singing. Here perceptive knowledge must directly guide action; its passage through reflection makes it uncertain, for it divides the attention and confuses the man. Thus savages and untaught men, who are little accustomed to think, perform certain physical exercises, fight with beasts, shoot with bows and arrows and the like, with a certainty and

rapidity which the reflecting European never attains to, just because his deliberation makes him hesitate and delay. For he tries, for example, to hit the right position or the right point of time, by finding out the mean between two false extremes; while the savage hits it directly without thinking of the false courses open to him. In the same way it is of no use to me to know in the abstract the exact angle, in degrees and minutes, at which I must apply a razor, if I do not know it intuitively, that is, if I have not got it in my touch. The knowledge of physiognomy also, is interfered with by the application of reason. This knowledge must be gained directly through the understanding. We say that the expression, the meaning of the features, can only be *felt*, that is, it cannot be put into abstract concepts. Every man has his direct intuitive method of physiognomy and pathognomy, yet one man understands more clearly than another these *signatura rerum*. But an abstract science of physiognomy to be taught and learned is not possible; for the distinctions of difference are here so fine that concepts cannot reach them; therefore abstract knowledge is related to them as a mosaic is to a painting by a Van der Werft or a Denner. In mosaics, however fine they may be, the limits of the stones are always there, and therefore no continuous passage from one colour to another is possible, and this is also the case with regard to concepts, with their rigidity and sharp delineation; however finely we may divide them by exact definition, they are still incapable of reaching the finer modifications of the perceptible, and this is just what happens in the example we have taken, knowledge of physiognomy.[16]

This quality of concepts by which they resemble the stones of a mosaic, and on account of which perception always remains their asymptote, is also the reason why nothing good is produced in art by their means. If the singer or the virtuoso attempts to guide his execution by reflection he remains silent. And this is equally true of the composer, the painter, and the poet. The concept always remains unfruitful in art; it can only direct the technical part of it, its sphere is science. We shall consider more fully in the third book, why all true art proceeds from sensuous knowledge, never from the concept. Indeed, with regard to behaviour also, and personal agreeableness in society, the concept has only a negative value in restraining the grosser manifestations of egotism and brutality; so that a polished manner is its commendable production. But all that is attractive, gracious, charming in behaviour, all affectionateness and friendliness, must not proceed from the concepts, for if it does, "we feel intention, and are put out of tune." All

dissimulation is the work of reflection; but it cannot be maintained constantly and without interruption: "*nemo potest personam diu ferre fictum*," says Seneca in his book *de clementia*; and so it is generally found out and loses its effect. Reason is needed in the full stress of life, where quick conclusions, bold action, rapid and sure comprehension are required, but it may easily spoil all if it gains the upper hand, and by perplexing hinders the intuitive, direct discovery, and grasp of the right by simple understanding, and thus induces irresolution.

Lastly, virtue and holiness do not proceed from reflection, but from the inner depths of the will, and its relation to knowledge. The exposition of this belongs to another part of our work; this, however, I may remark here, that the dogmas relating to ethics may be the same in the reason of whole nations, but the action of every individual different; and the converse also holds good; action, we say, is guided by *feelings*, — that is, simply not by concepts, but as a matter of fact by the ethical character. Dogmas occupy the idle reason; but action in the end pursues its own course independently of them, generally not according to abstract rules, but according to unspoken maxims, the expression of which is the whole man himself. Therefore, however different the religious dogmas of nations may be, yet in the case of all of them, a good action is accompanied by unspeakable satisfaction, and a bad action by endless remorse. No mockery can shake the former; no priest's absolution can deliver from the latter. Notwithstanding this, we must allow, that for the pursuit of a virtuous life, the application of reason is needful; only it is not its source, but has the subordinate function of preserving resolutions which have been made, of providing maxims to withstand the weakness of the moment, and give consistency to action. It plays the same part ultimately in art also, where it has just as little to do with the essential matter, but assists in carrying it out, for genius is not always at call, and yet the work must be completed in all its parts and rounded off to a whole.[17]

§ 13. All these discussions of the advantages and disadvantages of the application of reason are intended to show, that although abstract rational knowledge is the reflex of ideas of perception, and is founded on them, it is by no means in such entire congruity with them that it could everywhere take their place: indeed it never corresponds to them quite accurately. And thus, as we have seen, many human actions can only be performed by the

help of reason and deliberation, and yet there are some which are better performed without its assistance. This very incongruity of sensuous and abstract knowledge, on account of which the latter always merely approximates to the former, as mosaic approximates to painting, is the cause of a very remarkable phenomenon which, like reason itself, is peculiar to human nature, and of which the explanations that have ever anew been attempted, are insufficient: I mean *laughter*. On account of the source of this phenomenon, we cannot avoid giving the explanation of it here, though it again interrupts the course of our work to do so. The cause of laughter in every case is simply the sudden perception of the incongruity between a concept and the real objects which have been thought through it in some relation, and laughter itself is just the expression of this incongruity. It often occurs in this way: two or more real objects are thought through *one* concept, and the identity of the concept is transferred to the objects; it then becomes strikingly apparent from the entire difference of the objects in other respects, that the concept was only applicable to them from a one-sided point of view. It occurs just as often, however, that the incongruity between a single real object and the concept under which, from one point of view, it has rightly been subsumed, is suddenly felt. Now the more correct the subsumption of such objects under a concept may be from one point of view, and the greater and more glaring their incongruity with it, from another point of view, the greater is the ludicrous effect which is produced by this contrast. All laughter then is occasioned by a paradox, and therefore by unexpected subsumption, whether this is expressed in words or in actions. This, briefly stated, is the true explanation of the ludicrous.

I shall not pause here to relate anecdotes as examples to illustrate my theory; for it is so simple and comprehensible that it does not require them, and everything ludicrous which the reader may remember is equally valuable as a proof of it. But the theory is confirmed and illustrated by distinguishing two species into which the ludicrous is divided, and which result from the theory. Either, we have previously known two or more very different real objects, ideas of sense-perception, and have intentionally identified them through the unity of a concept which comprehends them both; this species of the ludicrous is called *wit*. Or, conversely, the concept is first present in knowledge, and we pass from it to reality, and to operation upon it, to action: objects which in other respects are fundamentally different, but which are all thought in that one concept, are now regarded

and treated in the same way, till, to the surprise and astonishment of the person acting, the great difference of their other aspects appears: this species of the ludicrous is called *folly*. Therefore everything ludicrous is either a flash of wit or a foolish action, according as the procedure has been from the discrepancy of the objects to the identity of the concept, or the converse; the former always intentional, the latter always unintentional, and from without. To seem to reverse the starting-point, and to conceal wit with the mask of folly, is the art of the jester and the clown. Being quite aware of the diversity of the objects, the jester unites them, with secret wit, under one concept, and then starting from this concept he receives from the subsequently discovered diversity of the objects the surprise which he himself prepared. It follows from this short but sufficient theory of the ludicrous, that, if we set aside the last case, that of the jester, wit must always show itself in words, folly generally in actions, though also in words, when it only expresses an intention and does not actually carry it out, or when it shows itself merely in judgments and opinions.

Pedantry is a form of folly. It arises in this way: a man lacks confidence in his own understanding, and, therefore, does not wish to trust to it, to recognise what is right directly in the particular case. He, therefore, puts it entirely under the control of the reason, and seeks to be guided by reason in everything; that is to say, he tries always to proceed from general concepts, rules, and maxims, and to confine himself strictly to them in life, in art, and even in moral conduct. Hence that clinging to the form, to the manner, to the expression and word which is characteristic of pedantry, and which with it takes the place of the real nature of the matter. The incongruity then between the concept and reality soon shows itself here, and it becomes evident that the former never condescends to the particular case, and that with its generality and rigid definiteness it can never accurately apply to the fine distinctions of difference and innumerable modifications of the actual. Therefore, the pedant, with his general maxims, almost always misses the mark in life, shows himself to be foolish, awkward, useless. In art, in which the concept is unfruitful, he produces lifeless, stiff, abortive mannerisms. Even with regard to ethics, the purpose to act rightly or nobly cannot always be carried out in accordance with abstract maxims; for in many cases the excessively nice distinctions in the nature of the circumstances necessitate a choice of the right proceeding directly from the character; for the application of mere abstract maxims sometimes gives false results, because

the maxims only half apply; and sometimes cannot be carried out, because they are foreign to the individual character of the actor, and this never allows itself to be entirely discovered; therefore, inconsistencies arise. Since then Kant makes it a condition of the moral worth of an action, that it shall proceed from pure rational abstract maxims, without any inclination or momentary emotion, we cannot entirely absolve him from the reproach of encouraging moral pedantry. This reproach is the significance of Schiller's epigram, entitled "Scruples of Conscience." When we speak, especially in connection with politics, of doctrinaires, theorists, savants, and so forth, we mean pedants, that is, persons who know the things well in the abstract, but not in the concrete. Abstraction consists in thinking away the less general predicates; but it is precisely upon these that so much depends in practice.

To complete our theory it remains for us to mention a spurious kind of wit, the play upon words, the *calembourg*, the pun, to which may be added the equivocation, the *double entendre*, the chief use of which is the expression of what is obscene. Just as the witticism brings two very different real objects under one concept, the pun brings two different concepts, by the assistance of accident, under one word. The same contrast appears, only familiar and more superficial, because it does not spring from the nature of things, but merely from the accident of nomenclature. In the case of the witticism the identity is in the concept, the difference in the reality, but in the case of the pun the difference is in the concepts and the identity in the reality, for the terminology is here the reality. It would only be a somewhat far-fetched comparison if we were to say that the pun is related to the witticism as the parabola (*sic*) of the upper inverted cone to that of the lower. The misunderstanding of the word or the *quid pro quo* is the unintentional pun, and is related to it exactly as folly is to wit. Thus the deaf man often affords occasion for laughter, just as much as the fool, and inferior writers of comedy often use the former for the latter to raise a laugh.

I have treated laughter here only from the psychical side; with regard to the physical side, I refer to what is said on the subject in the "Parerga," vol. II. ch. vi., § 98.[18]

§ 14. By means of these various discussions it is hoped that both the difference and the relation between the process of knowledge that belongs to the reason, rational knowledge, the concept on the one hand, and the direct knowledge in purely sensuous, mathematical intuition or perception,

and apprehension by the understanding on the other hand, has been clearly brought out. This remarkable relation of our kinds of knowledge led us almost inevitably to give, in passing, explanations of feeling and of laughter, but from all this we now turn back to the further consideration of science as the third great benefit which reason confers on man, the other two being speech and deliberate action. The general discussion of science which now devolves upon us, will be concerned partly with its form, partly with the foundation of its judgments, and lastly with its content.

We have seen that, with the exception of the basis of pure logic, rational knowledge in general has not its source in the reason itself; but having been otherwise obtained as knowledge of perception, it is stored up in the reason, for through reason it has entirely changed its character, and has become abstract knowledge. All rational knowledge, that is, knowledge that has been raised to consciousness in the abstract, is related to science strictly so called, as a fragment to the whole. Every one has gained a rational knowledge of many different things through experience, through consideration of the individual objects presented to him, but only he who sets himself the task of acquiring a complete knowledge in the abstract of a particular class of objects, strives after science. This class can only be marked off by means of a concept; therefore, at the beginning of every science there stands a concept, and by means of it the class of objects concerning which this science promises a complete knowledge in the abstract, is separated in thought from the whole world of things. For example, the concept of space-relations, or of the action of unorganised bodies upon each other, or of the nature of plants, or of animals, or of the successive changes of the surface of the globe, or of the changes of the human race as a whole, or of the construction of a language, and so forth. If science sought to obtain the knowledge of its object, by investigating each individual thing that is thought through the concept, till by degrees it had learned the whole, no human memory would be equal to the task, and no certainty of completeness would be obtainable. Therefore, it makes use of that property of concept-spheres explained above, that they include each other, and it concerns itself mainly with the wider spheres which lie within the concept of its object in general. When the relations of these spheres to each other have been determined, all that is thought in them is also generally determined, and can now be more and more accurately determined by the separation of smaller and smaller concept-spheres. In this

way it is possible for a science to comprehend its object completely. This path which it follows to knowledge, the path from the general to the particular, distinguishes it from ordinary rational knowledge; therefore, systematic form is an essential and characteristic feature of science. The combination of the most general concept-spheres of every science, that is, the knowledge of its first principles, is the indispensable condition of mastering it; how far we advance from these to the more special propositions is a matter of choice, and does not increase the thoroughness but only the extent of our knowledge of the science. The number of the first principles to which all the rest are subordinated, varies greatly in the different sciences, so that in some there is more subordination, in others more co-ordination; and in this respect, the former make greater claims upon the judgment, the latter upon the memory. It was known to the schoolmen,[19] that, as the syllogism requires two premises, no science can proceed from a single first principle which cannot be the subject of further deduction, but must have several, at least two. The specially classifying sciences: Zoology, Botany, and also Physics and Chemistry, inasmuch as they refer all inorganic action to a few fundamental forces, have most subordination; history, on the other hand, has really none at all; for the general in it consists merely in the survey of the principal periods, from which, however, the particular events cannot be deduced, and are only subordinated to them according to time, but according to the concept are co-ordinate with them. Therefore, history, strictly speaking, is certainly rational knowledge, but is not science. In mathematics, according to Euclid's treatment, the axioms alone are indemonstrable first principles, and all demonstrations are in gradation strictly subordinated to them. But this method of treatment is not essential to mathematics, and in fact each proposition introduces quite a new space construction, which in itself is independent of those which precede it, and indeed can be completely comprehended from itself, quite independently of them, in the pure intuition or perception of space, in which the most complicated construction is just as directly evident as the axiom; but of this more fully hereafter. Meanwhile every mathematical proposition remains always a universal truth, which is valid for innumerable particular cases; and a graduated process from the simple to the complicated propositions which are to be deduced from them, is also essential to mathematics; therefore, in every respect mathematics is a science. The completeness of a science as such, that is, in respect of form,

consists in there being as much subordination and as little co-ordination of the principles as possible. Scientific talent in general is, therefore, the faculty of subordinating the concept-spheres according to their different determinations, so that, as Plato repeatedly counsels, a science shall not be constituted by a general concept and an indefinite multiplicity immediately under it, but that knowledge shall descend by degrees from the general to the particular, through intermediate concepts and divisions, according to closer and closer definitions. In Kantian language this is called satisfying equally the law of homogeneity and that of specification. It arises from this peculiar nature of scientific completeness, that the aim of science is not greater certainty — for certainty may be possessed in just as high a degree by the most disconnected particular knowledge — but its aim is rather the facilitating of rational knowledge by means of its form, and the possibility of the completeness of rational knowledge which this form affords. It is therefore a very prevalent but perverted opinion that the scientific character of knowledge consists in its greater certainty, and just as false is the conclusion following from this, that, strictly speaking, the only sciences are mathematics and logic, because only in them, on account of their purely *a priori* character, is there unassailable certainty of knowledge. This advantage cannot be denied them, but it gives them no special claim to be regarded as sciences; for the special characteristic of science does not lie in certainty but in the systematic form of knowledge, based on the gradual descent from the general to the particular. The process of knowledge from the general to the particular, which is peculiar to the sciences, involves the necessity that in the sciences much should be established by deduction from preceding propositions, that is to say, by demonstration; and this has given rise to the old mistake that only what has been demonstrated is absolutely true, and that every truth requires a demonstration; whereas, on the contrary, every demonstration requires an undemonstrated truth, which ultimately supports it, or it may be, its own demonstration. Therefore a directly established truth is as much to be preferred to a truth established by demonstration as water from the spring is to water from the aqueduct. Perception, partly pure *a priori*, as it forms the basis of mathematics, partly empirical *a posteriori*, as it forms the basis of all the other sciences, is the source of all truth and the foundation of all science. (Logic alone is to be excepted, which is not founded upon perception but yet upon *direct* knowledge by the reason of its own laws.) Not the demonstrated judgments

nor their demonstrations, but judgments which are created directly out of perception, and founded upon it rather than on any demonstrations, are to science what the sun is to the world; for all light proceeds from them, and lighted by their light the others give light also. To establish the truth of such primary judgments directly from perception, to raise such strongholds of science from the innumerable multitude of real objects, that is the work of the *faculty of judgment*, which consists in the power of rightly and accurately carrying over into abstract consciousness what is known in perception, and judgment is consequently the mediator between understanding and reason. Only extraordinary and exceptional strength of judgment in the individual can actually advance science; but every one who is possessed of a healthy reason is able to deduce propositions from propositions, to demonstrate, to draw conclusions. To lay down and make permanent for reflection, in suitable concepts, what is known through perception, so that, on the one hand, what is common to many real objects is thought through *one* concept, and, on the other hand, their points of difference are each thought through one concept, so that the different shall be known and thought as different in spite of a partial agreement, and the identical shall be known and thought as identical in spite of a partial difference, all in accordance with the end and intention which in each case is in view; all this is done by the *faculty of judgment*. Deficiency in judgment is *silliness*. The silly man fails to grasp, now the partial or relative difference of concepts which in one aspect are identical, now the identity of concepts which are relatively or partially different. To this explanation of the faculty of judgment, moreover, Kant's division of it into reflecting and subsuming judgment may be applied, according as it passes from the perceived objects to the concepts, or from the latter to the former; in both cases always mediating between empirical knowledge of the understanding and the reflective knowledge of the reason. There can be no truth which could be brought out by means of syllogisms alone; and the necessity of establishing truth by means of syllogisms is merely relative, indeed subjective. Since all demonstration is syllogistic, in the case of a new truth we must first seek, not for a demonstration, but for direct evidence, and only in the absence of such evidence is a demonstration to be temporarily made use of. No science is susceptible of demonstration throughout any more than a building can stand in the air; all its demonstrations must ultimately rest upon what is perceived, and consequently cannot be

demonstrated, for the whole world of reflection rests upon and is rooted in the world of perception. All primal, that is, original, *evidence* is a *perception*, as the word itself indicates. Therefore it is either empirical or founded upon the perception *a priori* of the conditions of possible experience. In both cases it affords only immanent, not transcendent knowledge. Every concept has its worth and its existence only in its relation, sometimes very indirect, to an idea of perception; what is true of the concepts is also true of the judgments constructed out of them, and of all science. Therefore it must in some way be possible to know directly without demonstrations or syllogisms every truth that is arrived at through syllogisms and communicated by demonstrations. This is most difficult in the case of certain complicated mathematical propositions at which we only arrive by chains of syllogisms; for example, the calculation of the chords and tangents to all arcs by deduction from the proposition of Pythagoras. But even such a truth as this cannot essentially and solely rest upon abstract principles, and the space-relations which lie at its foundation also must be capable of being so presented *a priori* in pure intuition or perception that the truth of their abstract expression is directly established. But of mathematical demonstration we shall speak more fully shortly.

It is true we often hear men speak in a lofty strain of sciences which rest entirely upon correct conclusions drawn from sure premises, and which are consequently unassailable. But through pure logical reasoning, however true the premises may be, we shall never receive more than an articulate expression and exposition of what lies already complete in the premises; thus we shall only *explicitly* expound what was already *implicitly* understood. The esteemed sciences referred to are, however, specially the mathematical sciences, particularly astronomy. But the certainty of astronomy arises from the fact that it has for its basis the intuition or perception of space, which is given *a priori*, and is therefore infallible. All space-relations, however, follow from each other with a necessity (ground of being) which affords *a priori* certainty, and they can therefore be safely deduced from each other. To these mathematical properties we have only to add one force of nature, gravity, which acts precisely in relation to the masses and the square of the distance; and, lastly, the law of inertia, which follows from the law of causality and is therefore true *a priori*, and with it the empirical datum of the motion impressed, once for all, upon each of these masses. This is the whole material of astronomy, which both by its

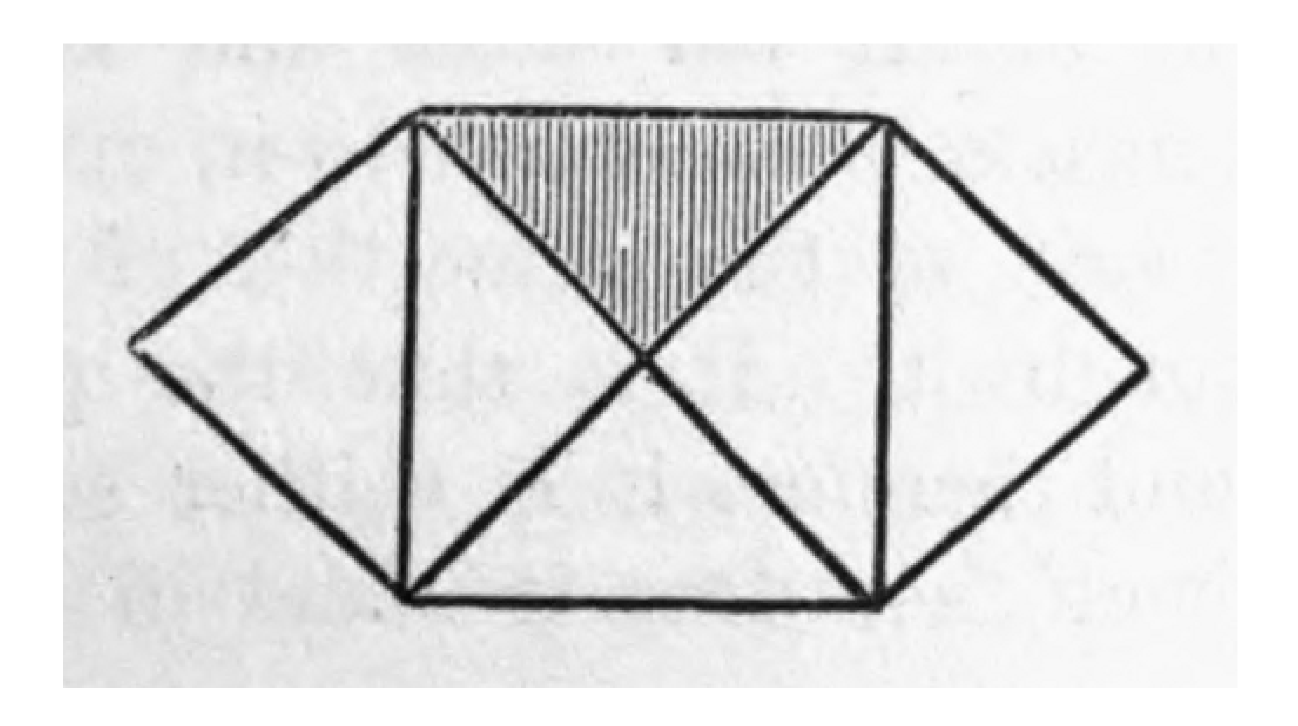
simplicity and its certainty leads to definite results, which are highly interesting on account of the vastness and importance of the objects. For example, if I know the mass of a planet and the distance of its satellite from it, I can tell with certainty the period of the revolution of the latter according to Kepler's second law. But the ground of this law is, that with this distance only this velocity will both chain the satellite to the planet and prevent it from falling into it. Thus it is only upon such a geometrical basis, that is, by means of an intuition or perception *a priori*, and also under the application of a law of nature, that much can be arrived at by means of syllogisms, for here they are merely like bridges from *one* sensuous apprehension to others; but it is not so with mere pure syllogistic reasoning in the exclusively logical method. The source of the first fundamental truths of astronomy is, however, properly induction, that is, the comprehension of what is given in many perceptions in one true and directly founded judgment. From this, hypotheses are afterwards constructed, and their confirmation by experience, as induction approaching to completeness, affords the proof of the first judgment. For example, the apparent motion of the planets is known empirically; after many false hypotheses with regard to the spacial connection of this motion (planetary course) the right one was at last found, then the laws which it obeyed (the laws of Kepler), and, lastly, the cause of these laws (universal gravitation), and the empirically known agreement of all observed cases with the whole of the hypotheses, and with their consequences, that is to say, induction, established them with complete certainty. The invention of the hypotheses was the work of the judgment, which rightly comprehended the given facts and expressed them accordingly; but induction, that is, a multitude of perceptions, confirmed their truth. But their truth could also be known directly, and by a single empirical perception, if we could pass freely through space and had telescopic eyes. Therefore, here also syllogisms are not the essential and only source of knowledge, but really only a makeshift.

As a third example taken from a different sphere we may mention that the so-called metaphysical truths, that is, such truths as those to which Kant assigns the position of the metaphysical first principles of natural science, do not owe their evidence to demonstration. What is *a priori* certain we know directly; as the form of all knowledge, it is known to us with the most complete necessity. For example, that matter is permanent, that is, can neither come into being nor pass away, we know directly as negative truth;

for our pure intuition or perception of space and time gives the possibility of motion; in the law of causality the understanding affords us the possibility of change of form and quality, but we lack powers of the imagination for conceiving the coming into being or passing away of matter. Therefore that truth has at all times been evident to all men everywhere, nor has it ever been seriously doubted; and this could not be the case if it had no other ground of knowledge than the abstruse and exceedingly subtle proof of Kant. But besides this, I have found Kant's proof to be false (as is explained in the Appendix), and have shown above that the permanence of matter is to be deduced, not from the share which time has in the possibility of experience, but from the share which belongs to space. The true foundation of all truths which in this sense are called metaphysical, that is, abstract expressions of the necessary and universal forms of knowledge, cannot itself lie in abstract principles; but only in the immediate consciousness of the forms of the idea communicating itself in apodictic assertions *a priori*, and fearing no refutation. But if we yet desire to give a proof of them, it can only consist in showing that what is to be proved is contained in some truth about which there is no doubt, either as a part of it or as a presupposition. Thus, for example, I have shown that all empirical perception implies the application of the law of causality, the knowledge of which is hence a condition of all experience, and therefore cannot be first given and conditioned through experience as Hume thought. Demonstrations in general are not so much for those who wish to learn as for those who wish to dispute. Such persons stubbornly deny directly established insight; now only the truth can be consistent in all directions, and therefore we must show such persons that they admit under *one* form and indirectly, what they deny under another form and directly; that is, the logically necessary connection between what is denied and what is admitted.

It is also a consequence of the scientific form, the subordination of everything particular under a general, and so on always to what is more general, that the truth of many propositions is only logically proved, — that is, through their dependence upon other propositions, through syllogisms, which at the same time appear as proofs. But we must never forget that this whole form of science is merely a means of rendering knowledge more easy, not a means to greater certainty. It is easier to discover the nature of an animal, by means of the species to which it belongs, and so on through the

genus, family, order, and class, than to examine on every occasion the animal presented to us: but the truth of all propositions arrived at syllogistically is always conditioned by and ultimately dependent upon some truth which rests not upon reasoning but upon perception. If this perception were always as much within our reach as a deduction through syllogisms, then it would be in every respect preferable. For every deduction from concepts is exposed to great danger of error, on account of the fact we have considered above, that so many spheres lie partly within each other, and that their content is often vague or uncertain. This is illustrated by a multitude of demonstrations of false doctrines and sophisms of every kind. Syllogisms are indeed perfectly certain as regards form, but they are very uncertain on account of their matter, the concepts. For, on the one hand, the spheres of these are not sufficiently sharply defined, and, on the other hand, they intersect each other in so many ways that one sphere is in part contained in many others, and we may pass at will from it to one or another of these, and from this sphere again to others, as we have already shown. Or, in other words, the minor term and also the middle can always be subordinated to different concepts, from which we may choose at will the major and the middle, and the nature of the conclusion depends on this choice. Consequently immediate evidence is always much to be preferred to reasoned truth, and the latter is only to be accepted when the former is too remote, and not when it is as near or indeed nearer than the latter. Accordingly we saw above that, as a matter of fact, in the case of logic, in which the immediate knowledge in each individual case lies nearer to hand than deduced scientific knowledge, we always conduct our thought according to our immediate knowledge of the laws of thought, and leave logic unused.[20]



§ 15. If now with our conviction that perception is the primary source of all evidence, and that only direct or indirect connection with it is absolute truth; and further, that the shortest way to this is always the surest, as every interposition of concepts means exposure to many deceptions; if, I say, we now turn with this conviction to mathematics, as it was established as a science by Euclid, and has remained as a whole to our own day, we cannot help regarding the method it adopts, as strange and indeed perverted. We ask that every logical proof shall be traced back to an origin in perception; but mathematics, on the contrary, is at great pains deliberately to throw away the evidence of perception which is peculiar to it, and always at hand,

that it may substitute for it a logical demonstration. This must seem to us like the action of a man who cuts off his legs in order to go on crutches, or like that of the prince in the "*Triumph der Empfindsamkeit*" who flees from the beautiful reality of nature, to delight in a stage scene that imitates it. I must here refer to what I have said in the sixth chapter of the essay on the principle of sufficient reason, and take for granted that it is fresh and present in the memory of the reader; so that I may link my observations on to it without explaining again the difference between the mere ground of knowledge of a mathematical truth, which can be given logically, and the ground of being, which is the immediate connection of the parts of space and time, known only in perception. It is only insight into the ground of being that secures satisfaction and thorough knowledge. The mere ground of knowledge must always remain superficial; it can afford us indeed rational knowledge *that* a thing is as it is, but it cannot tell *why* it is so. Euclid chose the latter way to the obvious detriment of the science. For just at the beginning, for example, when he ought to show once for all how in a triangle the angles and sides reciprocally determine each other, and stand to each other in the relation of reason and consequent, in accordance with the form which the principle of sufficient reason has in pure space, and which there, as in every other sphere, always affords the necessity that a thing is as it is, because something quite different from it, is as it is; instead of in this way giving a thorough insight into the nature of the triangle, he sets up certain disconnected arbitrarily chosen propositions concerning the triangle, and gives a logical ground of knowledge of them, through a laborious logical demonstration, based upon the principle of contradiction. Instead of an exhaustive knowledge of these space-relations we therefore receive merely certain results of them, imparted to us at pleasure, and in fact we are very much in the position of a man to whom the different effects of an ingenious machine are shown, but from whom its inner connection and construction are withheld. We are compelled by the principle of contradiction to admit that what Euclid demonstrates is true, but we do not comprehend *why* it is so. We have therefore almost the same uncomfortable feeling that we experience after a juggling trick, and, in fact, most of Euclid's demonstrations are remarkably like such feats. The truth almost always enters by the back door, for it manifests itself *per accidens* through some contingent circumstance. Often a *reductio ad absurdum* shuts all the doors one after another, until only one is left through which we are

therefore compelled to enter. Often, as in the proposition of Pythagoras, lines are drawn, we don't know why, and it afterwards appears that they were traps which close unexpectedly and take prisoner the assent of the astonished learner, who must now admit what remains wholly inconceivable in its inner connection, so much so, that he may study the whole of Euclid through and through without gaining a real insight into the laws of space-relations, but instead of them he only learns by heart certain results which follow from them. This specially empirical and unscientific knowledge is like that of the doctor who knows both the disease and the cure for it, but does not know the connection between them. But all this is the necessary consequence if we capriciously reject the special kind of proof and evidence of one species of knowledge, and forcibly introduce in its stead a kind which is quite foreign to its nature. However, in other respects the manner in which this has been accomplished by Euclid deserves all the praise which has been bestowed on him through so many centuries, and which has been carried so far that his method of treating mathematics has been set up as the pattern of all scientific exposition. Men tried indeed to model all the sciences after it, but later they gave up the attempt without quite knowing why. Yet in our eyes this method of Euclid in mathematics can appear only as a very brilliant piece of perversity. But when a great error in life or in science has been intentionally and methodically carried out with universal applause, it is always possible to discover its source in the philosophy which prevailed at the time. The Eleatics first brought out the difference, and indeed often the conflict, that exists between what is perceived, φαινομενον,[21] and what is thought, νουμενον, and used it in many ways in their philosophical epigrams, and also in sophisms. They were followed later by the Megarics, the Dialecticians, the Sophists, the New-Academy, and the Sceptics; these drew attention to the illusion, that is to say, to the deception of the senses, or rather of the understanding which transforms the data of the senses into perception, and which often causes us to see things to which the reason unhesitatingly denies reality; for example, a stick broken in water, and such like. It came to be known that sense-perception was not to be trusted unconditionally, and it was therefore hastily concluded that only rational, logical thought could establish truth; although Plato (in the Parmenides), the Megarics, Pyrrho, and the New-Academy, showed by examples (in the manner which was afterwards adopted by Sextus Empiricus) how

syllogisms and concepts were also sometimes misleading, and indeed produced paralogisms and sophisms which arise much more easily and are far harder to explain than the illusion of sense-perception. However, this rationalism, which arose in opposition to empiricism, kept the upper hand, and Euclid constructed the science of mathematics in accordance with it. He was compelled by necessity to found the axioms upon evidence of perception (φαινομενον), but all the rest he based upon reasoning (νουμενον). His method reigned supreme through all the succeeding centuries, and it could not but do so as long as pure intuition or perception, *a priori*, was not distinguished from empirical perception. Certain passages from the works of Proclus, the commentator of Euclid, which Kepler translated into Latin in his book, "De Harmonia Mundi," seem to show that he fully recognised this distinction. But Proclus did not attach enough importance to the matter; he merely mentioned it by the way, so that he remained unnoticed and accomplished nothing. Therefore, not till two thousand years later will the doctrine of Kant, which is destined to make such great changes in all the knowledge, thought, and action of European nations, produce this change in mathematics also. For it is only after we have learned from this great man that the intuitions or perceptions of space and time are quite different from empirical perceptions, entirely independent of any impression of the senses, conditioning it, not conditioned by it, *i.e.*, are *a priori*, and therefore are not exposed to the illusions of sense; only after we have learned this, I say, can we comprehend that Euclid's logical method of treating mathematics is a useless precaution, a crutch for sound legs, that it is like a wanderer who during the night mistakes a bright, firm road for water, and carefully avoiding it, toils over the broken ground beside it, content to keep from point to point along the edge of the supposed water. Only now can we affirm with certainty that what presents itself to us as necessary in the perception of a figure, does not come from the figure on the paper, which is perhaps very defectively drawn, nor from the abstract concept under which we think it, but immediately from the form of all knowledge of which we are conscious *a priori*. This is always the principle of sufficient reason; here as the form of perception, *i.e.*, space, it is the principle of the ground of being, the evidence and validity of which is, however, just as great and as immediate as that of the principle of the ground of knowing, *i.e.*, logical certainty. Thus we need not and ought not to leave the peculiar province of

mathematics in order to put our trust only in logical proof, and seek to authenticate mathematics in a sphere which is quite foreign to it, that of concepts. If we confine ourselves to the ground peculiar to mathematics, we gain the great advantage that in it the rational knowledge *that* something is, is one with the knowledge *why* it is so, whereas the method of Euclid entirely separates these two, and lets us know only the first, not the second. Aristotle says admirably in the Analyt., post. i. 27: “Ακριβεστερα δ᾽ επιστημη επιστημης και προτερα, ἡτε του ὁτι και του διοτι ἡ αυτη, αλλα μη χωρις του ὁτι, της του διοτι” (*Subtilior autem et praestantior ea est scientia, quâ* quod *aliquid sit, et* cur *sit una simulque intelligimus non separatim* quod, *et* cur *sit*). In physics we are only satisfied when the knowledge that a thing is as it is is combined with the knowledge why it is so. To know that the mercury in the Torricellian tube stands thirty inches high is not really rational knowledge if we do not know that it is sustained at this height by the counterbalancing weight of the atmosphere. Shall we then be satisfied in mathematics with the *qualitas occulta* of the circle that the segments of any two intersecting chords always contain equal rectangles? That it is so Euclid certainly demonstrates in the 35th Prop. of the Third Book; *why* it is so remains doubtful. In the same way the proposition of Pythagoras teaches us a *qualitas occulta* of the right-angled triangle; the stilted and indeed fallacious demonstration of Euclid forsakes us at the *why*, and a simple figure, which we already know, and which is present to us, gives at a glance far more insight into the matter, and firm inner conviction of that necessity, and of the dependence of that quality upon the right angle: —

In the case of unequal catheti also, and indeed generally in the case of every possible geometrical truth, it is quite possible to obtain such a conviction based on perception, because these truths were always discovered by such an empirically known necessity, and their demonstration was only thought out afterwards in addition. Thus we only require an analysis of the process of thought in the first discovery of a geometrical truth in order to know its necessity empirically. It is the analytical method in general that I wish for the exposition of mathematics, instead of the synthetical method which Euclid made use of. Yet this would have very great, though not insuperable, difficulties in the case of complicated mathematical truths. Here and there in Germany men are beginning to alter the exposition of mathematics, and to proceed more in this analytical way. The greatest effort in this direction has been made by Herr Kosack, teacher of mathematics and physics in the Gymnasium at Nordhausen, who added a thorough attempt to teach geometry according to my principles to the programme of the school examination on the 6th of April 1852.

In order to improve the method of mathematics, it is especially necessary to overcome the prejudice that demonstrated truth has any superiority over what is known through perception, or that logical truth founded upon the principle of contradiction has any superiority over metaphysical truth, which is immediately evident, and to which belongs the pure intuition or perception of space.

That which is most certain, and yet always inexplicable, is what is involved in the principle of sufficient reason, for this principle, in its different aspects, expresses the universal form of all our ideas and knowledge. All explanation consists of reduction to it, exemplification in the particular case of the connection of ideas expressed generally through it. It is thus the principle of all explanation, and therefore it is neither susceptible of an explanation itself, nor does it stand in need of it; for every explanation presupposes it, and only obtains meaning through it. Now, none of its forms are superior to the rest; it is equally certain and incapable of demonstration as the principle of the ground of being, or of change, or of action, or of knowing. The relation of reason and consequent is a necessity in all its forms, and indeed it is, in general, the source of the concept of necessity, for necessity has no other meaning. If the reason is given there is no other necessity than that of the consequent, and there is no reason that does not involve the necessity of the consequent. Just as surely then as the consequent expressed in the conclusion follows from the ground of knowledge given in the premises, does the ground of being in space determine its consequent in space: if I know through perception the relation of these two, this certainty is just as great as any logical certainty. But every geometrical proposition is just as good an expression of such a relation as one of the twelve axioms; it is a metaphysical truth, and as such, just as certain as the principle of contradiction itself, which is a metalogical truth, and the common foundation of all logical demonstration. Whoever denies the necessity, exhibited for intuition or perception, of the space-relations expressed in any proposition, may just as well deny the axioms, or that the conclusion follows from the premises, or, indeed, he may as well deny the principle of contradiction itself, for all these relations are equally undemonstrable, immediately evident and known *a priori*. For any one to wish to derive the necessity of space-relations, known in intuition or perception, from the principle of contradiction by means of a logical demonstration is just the same as for the feudal superior of an estate to wish to hold it as the vassal of another. Yet this is what Euclid has done. His axioms only, he is compelled to leave resting upon immediate evidence; all the geometrical truths which follow are demonstrated logically, that is to say, from the agreement of the assumptions made in the proposition with the axioms which are presupposed, or with some earlier proposition; or from the contradiction between the opposite of the proposition and the

assumptions made in it, or the axioms, or earlier propositions, or even itself. But the axioms themselves have no more immediate evidence than any other geometrical problem, but only more simplicity on account of their smaller content.

When a criminal is examined, a *procès-verbal* is made of his statement in order that we may judge of its truth from its consistency. But this is only a makeshift, and we are not satisfied with it if it is possible to investigate the truth of each of his answers for itself; especially as he might lie consistently from the beginning. But Euclid investigated space according to this first method. He set about it, indeed, under the correct assumption that nature must everywhere be consistent, and that therefore it must also be so in space, its fundamental form. Since then the parts of space stand to each other in a relation of reason and consequent, no single property of space can be different from what it is without being in contradiction with all the others. But this is a very troublesome, unsatisfactory, and roundabout way to follow. It prefers indirect knowledge to direct, which is just as certain, and it separates the knowledge that a thing is from the knowledge why it is, to the great disadvantage of the science; and lastly, it entirely withholds from the beginner insight into the laws of space, and indeed renders him unaccustomed to the special investigation of the ground and inner connection of things, inclining him to be satisfied with a mere historical knowledge that a thing is as it is. The exercise of acuteness which this method is unceasingly extolled as affording consists merely in this, that the pupil practises drawing conclusions, *i.e.*, he practises applying the principle of contradiction, but specially he exerts his memory to retain all those data whose agreement is to be tested. Moreover, it is worth noticing that this method of proof was applied only to geometry and not to arithmetic. In arithmetic the truth is really allowed to come home to us through perception alone, which in it consists simply in counting. As the perception of numbers is in *time alone*, and therefore cannot be represented by a sensuous schema like the geometrical figure, the suspicion that perception is merely empirical, and possibly illusive, disappeared in arithmetic, and the introduction of the logical method of proof into geometry was entirely due to this suspicion. As time has only one dimension, counting is the only arithmetical operation, to which all others may be reduced; and yet counting is just intuition or perception *a priori*, to which there is no hesitation in appealing here, and through which alone everything else, every sum and

every equation, is ultimately proved. We prove, for example, not that $(7 + 9 \times 8 - 2)/3 = 42$; but we refer to the pure perception in time, counting thus makes each individual problem an axiom. Instead of the demonstrations that fill geometry, the whole content of arithmetic and algebra is thus simply a method of abbreviating counting. We mentioned above that our immediate perception of numbers in time extends only to about ten. Beyond this an abstract concept of the numbers, fixed by a word, must take the place of the perception; which does not therefore actually occur any longer, but is only indicated in a thoroughly definite manner. Yet even so, by the important assistance of the system of figures which enables us to represent all larger numbers by the same small ones, intuitive or perceptive evidence of every sum is made possible, even where we make such use of abstraction that not only the numbers, but indefinite quantities and whole operations are thought only in the abstract and indicated as so thought, as [sqrt](r^b) so that we do not perform them, but merely symbolise them.

We might establish truth in geometry also, through pure *a priori* perception, with the same right and certainty as in arithmetic. It is in fact always this necessity, known through perception in accordance with the principle of sufficient reason of being, which gives to geometry its principal evidence, and upon which in the consciousness of every one, the certainty of its propositions rests. The stilted logical demonstration is always foreign to the matter, and is generally soon forgotten, without weakening our conviction. It might indeed be dispensed with altogether without diminishing the evidence of geometry, for this is always quite independent of such demonstration, which never proves anything we are not convinced of already, through another kind of knowledge. So far then it is like a cowardly soldier, who adds a wound to an enemy slain by another, and then boasts that he slew him himself.[22]

After all this we hope there will be no doubt that the evidence of mathematics, which has become the pattern and symbol of all evidence, rests essentially not upon demonstration, but upon immediate perception, which is thus here, as everywhere else, the ultimate ground and source of truth. Yet the perception which lies at the basis of mathematics has a great advantage over all other perception, and therefore over empirical perception. It is *a priori*, and therefore independent of experience, which is always given only in successive parts; therefore everything is equally near to it, and we can start either from the reason or from the consequent, as we

please. Now this makes it absolutely reliable, for in it the consequent is known from the reason, and this is the only kind of knowledge that has necessity; for example, the equality of the sides is known as established by the equality of the angles. All empirical perception, on the other hand, and the greater part of experience, proceeds conversely from the consequent to the reason, and this kind of knowledge is not infallible, for necessity only attaches to the consequent on account of the reason being given, and no necessity attaches to the knowledge of the reason from the consequent, for the same consequent may follow from different reasons. The latter kind of knowledge is simply induction, *i.e.*, from many consequents which point to one reason, the reason is accepted as certain; but as the cases can never be all before us, the truth here is not unconditionally certain. But all knowledge through sense-perception, and the great bulk of experience, has only this kind of truth. The affection of one of the senses induces the understanding to infer a cause of the effect, but, as a conclusion from the consequent to the reason is never certain, illusion, which is deception of the senses, is possible, and indeed often occurs, as was pointed out above. Only when several of the senses, or it may be all the five, receive impressions which point to the same cause, the possibility of illusion is reduced to a minimum; but yet it still exists, for there are cases, for example, the case of counterfeit money, in which all the senses are deceived. All empirical knowledge, and consequently the whole of natural science, is in the same position, except only the pure, or as Kant calls it, metaphysical part of it. Here also the causes are known from the effects, consequently all natural philosophy rests upon hypotheses, which are often false, and must then gradually give place to more correct ones. Only in the case of purposely arranged experiments, knowledge proceeds from the cause to the effect, that is, it follows the method that affords certainty; but these experiments themselves are undertaken in consequence of hypotheses. Therefore, no branch of natural science, such as physics, or astronomy, or physiology could be discovered all at once, as was the case with mathematics and logic, but required and requires the collected and compared experiences of many centuries. In the first place, repeated confirmation in experience brings the induction, upon which the hypothesis rests, so near completeness that in practice it takes the place of certainty, and is regarded as diminishing the value of the hypothesis, its source, just as little as the incommensurability of straight and curved lines diminishes the value of the application of geometry, or that

perfect exactness of the logarithm, which is not attainable, diminishes the value of arithmetic. For as the logarithm, or the squaring of the circle, approaches infinitely near to correctness through infinite fractions, so, through manifold experience, the induction, *i.e.*, the knowledge of the cause from the effects, approaches, not infinitely indeed, but yet so near mathematical evidence, *i.e.*, knowledge of the effects from the cause, that the possibility of mistake is small enough to be neglected, but yet the possibility exists; for example, a conclusion from an indefinite number of cases to all cases, *i.e.*, to the unknown ground on which all depend, is an induction. What conclusion of this kind seems more certain than that all men have the heart on the left side? Yet there are extremely rare and quite isolated exceptions of men who have the heart upon the right side. Sense-perception and empirical science have, therefore, the same kind of evidence. The advantage which mathematics, pure natural science, and logic have over them, as *a priori* knowledge, rests merely upon this, that the formal element in knowledge upon which all that is *a priori* is based, is given as a whole and at once, and therefore in it we can always proceed from the cause to the effect, while in the former kind of knowledge we are generally obliged to proceed from the effect to the cause. In other respects, the law of causality, or the principle of sufficient reason of change, which guides empirical knowledge, is in itself just as certain as the other forms of the principle of sufficient reason which are followed by the *a priori* sciences referred to above. Logical demonstrations from concepts or syllogisms have the advantage of proceeding from the reason to the consequent, just as much as knowledge through perception *a priori*, and therefore in themselves, *i.e.*, according to their form, they are infallible. This has greatly assisted to bring demonstration in general into such esteem. But this infallibility is merely relative; the demonstration merely subsumes under the first principles of the science, and it is these which contain the whole material truth of science, and they must not themselves be demonstrated, but must be founded on perception. In the few *a priori* sciences we have named above, this perception is pure, but everywhere else it is empirical, and is only raised to universality through induction. If, then, in the empirical sciences also, the particular is proved from the general, yet the general, on the other hand, has received its truth from the particular; it is only a store of collected material, not a self-constituted foundation.

So much for the foundation of truth. Of the source and possibility of error many explanations have been tried since Plato's metaphorical solution of the dove-cot where the wrong pigeons are caught, &c. (Theætetus, p. 167, *et seq.*) Kant's vague, indefinite explanation of the source of error by means of the diagram of diagonal motion, will be found in the "Critique of Pure Reason," p. 294 of the first edition, and p. 350 of the fifth. As truth is the relation of a judgment to its ground of knowledge, it is always a problem how the person judging can believe that he has such a ground of knowledge and yet not have it; that is to say, how error, the deception of reason, is possible. I find this possibility quite analogous to that of illusion, or the deception of the understanding, which has been explained above. My opinion is (and this is what gives this explanation its proper place here) that *every error is an inference from the consequent to the reason*, which indeed is valid when we know that the consequent has that reason and can have no other; but otherwise is not valid. The person who falls into error, either attributes to a consequent a reason which it cannot have, in which case he shows actual deficiency of understanding, *i.e.*, deficiency in the capacity for immediate knowledge of the connection between the cause and the effect, or, as more frequently happens, he attributes to the effect a cause which is possible, but he adds to the major proposition of the syllogism, in which he infers the cause from the effect, that this effect *always* results only from this cause. Now he could only be assured of this by a complete induction, which, however, he assumes without having made it. This "always" is therefore too wide a concept, and instead of it he ought to have used "sometimes" or "generally." The conclusion would then be problematical, and therefore not erroneous. That the man who errs should proceed in this way is due either to haste, or to insufficient knowledge of what is possible, on account of which he does not know the necessity of the induction that ought to be made. Error then is quite analogous to illusion. Both are inferences from the effect to the cause; the illusion brought about always in accordance with the law of causality, and by the understanding alone, thus directly, in perception itself; the error in accordance with all the forms of the principle of sufficient reason, and by the reason, thus in thought itself; yet most commonly in accordance with the law of causality, as will appear from the three following examples, which may be taken as types or representatives of the three kinds of error. (1.) The illusion of the senses (deception of the understanding) induces error (deception of the reason); for

example, if one mistakes a painting for an alto-relief, and actually takes it for such; the error results from a conclusion from the following major premise: "If dark grey passes regularly through all shades to white; the cause is *always* the light, which strikes differently upon projections and depressions, *ergo* — ." (2.) "If there is no money in my safe, the cause is *always* that my servant has got a key for it: *ergo* — ." (3.) "If a ray of sunlight, broken through a prism, *i.e.*, bent up or down, appears as a coloured band instead of round and white as before, the cause must always be that light consists of homogeneous rays, differently coloured and refrangible to different degrees, which, when forced asunder on account of the difference of their refrangibility, give an elongated and variously-coloured spectrum: *ergo — bibamus!*" — It must be possible to trace every error to such a conclusion, drawn from a major premise which is often only falsely generalised, hypothetical, and founded on the assumption that some particular cause is that of a certain effect. Only certain mistakes in counting are to be excepted, and they are not really errors, but merely mistakes. The operation prescribed by the concepts of the numbers has not been carried out in pure intuition or perception, in counting, but some other operation instead of it.

As regards the *content* of the sciences generally, it is, in fact, always the relation of the phenomena of the world to each other, according to the principle of sufficient reason, under the guidance of the *why*, which has validity and meaning only through this principle. *Explanation* is the establishment of this relation. Therefore explanation can never go further than to show two ideas standing to each other in the relation peculiar to that form of the principle of sufficient reason which reigns in the class to which they belong. If this is done we cannot further be asked the question, *why*: for the relation proved is that one which absolutely cannot be imagined as other than it is, *i.e.*, it is the form of all knowledge. Therefore we do not ask why 2 + 2 = 4; or why the equality of the angles of a triangle determines the equality of the sides; or why its effect follows any given cause; or why the truth of the conclusion is evident from the truth of the premises. Every explanation which does not ultimately lead to a relation of which no "why" can further be demanded, stops at an accepted *qualitas occulta*; but this is the character of every original force of nature. Every explanation in natural science must ultimately end with such a *qualitas occulta*, and thus with complete obscurity. It must leave the inner nature of a stone just as much

unexplained as that of a human being; it can give as little account of the weight, the cohesion, the chemical qualities, &c., of the former, as of the knowing and acting of the latter. Thus, for example, weight is a *qualitas occulta*, for it can be thought away, and does not proceed as a necessity from the form of knowledge; which, on the contrary, is not the case with the law of inertia, for it follows from the law of causality, and is therefore sufficiently explained if it is referred to that law. There are two things which are altogether inexplicable, — that is to say, do not ultimately lead to the relation which the principle of sufficient reason expresses. These are, first, the principle of sufficient reason itself in all its four forms, because it is the principle of all explanation, which has meaning only in relation to it; secondly, that to which this principle does not extend, but which is the original source of all phenomena; the thing-in-itself, the knowledge of which is not subject to the principle of sufficient reason. We must be content for the present not to understand this thing-in-itself, for it can only be made intelligible by means of the following book, in which we shall resume this consideration of the possible achievements of the sciences. But at the point at which natural science, and indeed every science, leaves things, because not only its explanation of them, but even the principle of this explanation, the principle of sufficient reason, does not extend beyond this point; there philosophy takes them up and treats them after its own method, which is quite distinct from the method of science. In my essay on the principle of sufficient reason, § 51, I have shown how in the different sciences the chief guiding clue is one or other form of that principle; and, in fact, perhaps the most appropriate classification of the sciences might be based upon this circumstance. Every explanation arrived at by the help of this clue is, as we have said, merely relative; it explains things in relation to each other, but something which indeed is presupposed is always left unexplained. In mathematics, for example, this is space and time; in mechanics, physics, and chemistry it is matter, qualities, original forces and laws of nature; in botany and zoology it is the difference of species, and life itself; in history it is the human race with all its properties of thought and will: in all it is that form of the principle of sufficient reason which is respectively applicable. It is peculiar to *philosophy* that it presupposes nothing as known, but treats everything as equally external and a problem; not merely the relations of phenomena, but also the phenomena themselves, and even the principle of sufficient reason to which the other sciences are

content to refer everything. In philosophy nothing would be gained by such a reference, as one member of the series is just as external to it as another; and, moreover, that kind of connection is just as much a problem for philosophy as what is joined together by it, and the latter again is just as much a problem after its combination has been explained as before it. For, as we have said, just what the sciences presuppose and lay down as the basis and the limits of their explanation, is precisely and peculiarly the problem of philosophy, which may therefore be said to begin where science ends. It cannot be founded upon demonstrations, for they lead from known principles to unknown, but everything is equally unknown and external to philosophy. There can be no principle in consequence of which the world with all its phenomena first came into existence, and therefore it is not possible to construct, as Spinoza wished, a philosophy which demonstrates *ex firmis principiis*. Philosophy is the most general rational knowledge, the first principles of which cannot therefore be derived from another principle still more general. The principle of contradiction establishes merely the agreement of concepts, but does not itself produce concepts. The principle of sufficient reason explains the connections of phenomena, but not the phenomena themselves; therefore philosophy cannot proceed upon these principles to seek a *causa efficiens* or a *causa finalis* of the whole world. My philosophy, at least, does not by any means seek to know *whence* or *wherefore* the world exists, but merely *what* the world is. But the *why* is here subordinated to the *what*, for it already belongs to the world, as it arises and has meaning and validity only through the form of its phenomena, the principle of sufficient reason. We might indeed say that every one knows what the world is without help, for he is himself that subject of knowledge of which the world is the idea; and so far this would be true. But that knowledge is empirical, is in the concrete; the task of philosophy is to reproduce this in the abstract to raise to permanent rational knowledge the successive changing perceptions, and in general, all that is contained under the wide concept of feeling and merely negatively defined as not abstract, distinct, rational knowledge. It must therefore consist of a statement in the abstract, of the nature of the whole world, of the whole, and of all the parts. In order then that it may not lose itself in the endless multitude of particular judgments, it must make use of abstraction and think everything individual in the universal, and its differences also in the universal. It must therefore partly separate and partly unite, in order to

present to rational knowledge the whole manifold of the world generally, according to its nature, comprehended in a few abstract concepts. Through these concepts, in which it fixes the nature of the world, the whole individual must be known as well as the universal, the knowledge of both therefore must be bound together to the minutest point. Therefore the capacity for philosophy consists just in that in which Plato placed it, the knowledge of the one in the many, and the many in the one. Philosophy will therefore be a sum-total of general judgments, whose ground of knowledge is immediately the world itself in its entirety, without excepting anything; thus all that is to be found in human consciousness; it will be *a complete recapitulation, as it were, a reflection, of the world in abstract concepts*, which is only possible by the union of the essentially identical in *one* concept and the relegation of the different to another. This task was already prescribed to philosophy by Bacon of Verulam when he said: *ea demum vera est philosophia, quae mundi ipsius voces fidelissime reddit, et veluti dictante mundo conscripta est, et nihil aliud est, quam ejusdem* simulacrum et reflectio, *neque addit quidquam de proprio, sed tantum iterat et resonat* (De Augm. Scient., L. 2, c. 13). But we take this in a wider sense than Bacon could then conceive.

The agreement which all the sides and parts of the world have with each other, just because they belong to a whole, must also be found in this abstract copy of it. Therefore the judgments in this sum-total could to a certain extent be deduced from each other, and indeed always reciprocally so deduced. Yet to make the first judgment possible, they must all be present, and thus implied as prior to it in the knowledge of the world in the concrete, especially as all direct proof is more certain than indirect proof; their harmony with each other by virtue of which they come together into the unity of *one* thought, and which arises from the harmony and unity of the world of perception itself, which is their common ground of knowledge, is not therefore to be made use of to establish them, as that which is prior to them, but is only added as a confirmation of their truth. This problem itself can only become quite clear in being solved.[23]

§ 16. After this full consideration of reason as a special faculty of knowledge belonging to man alone, and the results and phenomena peculiar to human nature brought about by it, it still remains for me to speak of reason, so far as it is the guide of human action, and in this respect may be called *practical*. But what there is to say upon this point has found its place

elsewhere in the appendix to this work, where I controvert the existence of the so-called practical reason of Kant, which he (certainly very conveniently) explained as the immediate source of virtue, and as the seat of an absolute (*i.e.*, fallen from heaven) imperative. The detailed and thorough refutation of this Kantian principle of morality I have given later in the "Fundamental Problems of Ethics." There remains, therefore, but little for me to say here about the actual influence of reason, in the true sense of the word, upon action. At the commencement of our treatment of reason we remarked, in general terms, how much the action and behaviour of men differs from that of brutes, and that this difference is to be regarded as entirely due to the presence of abstract concepts in consciousness. The influence of these upon our whole existence is so penetrating and significant that, on account of them, we are related to the lower animals very much as those animals that see are related to those that have no eyes (certain larvae, worms, and zoophytes). Animals without eyes know only by touch what is immediately present to them in space, what comes into contact with them; those which see, on the contrary, know a wide circle of near and distant objects. In the same way the absence of reason confines the lower animals to the ideas of perception, *i.e.*, the real objects which are immediately present to them in time; we, on the contrary, on account of knowledge in the abstract, comprehend not only the narrow actual present, but also the whole past and future, and the wide sphere of the possible; we view life freely on all its sides, and go far beyond the present and the actual. Thus what the eye is in space and for sensuous knowledge, reason is, to a certain extent, in time and for inner knowledge. But as the visibility of objects has its worth and meaning only in the fact that it informs us of their tangibility, so the whole worth of abstract knowledge always consists in its relation to what is perceived. Therefore men naturally attach far more worth to immediate and perceived knowledge than to abstract concepts, to that which is merely thought; they place empirical knowledge before logical. But this is not the opinion of men who live more in words than in deeds, who have seen more on paper and in books than in actual life, and who in their greatest degeneracy become pedants and lovers of the mere letter. Thus only is it conceivable that Leibnitz and Wolf and all their successors could go so far astray as to explain knowledge of perception, after the example of Duns Scotus, as merely confused abstract knowledge! To the honour of Spinoza, I must mention that his truer sense led him, on the

contrary, to explain all general concepts as having arisen from the confusion of that which was known in perception (Eth. II., prop. 40, Schol. 1). It is also a result of perverted opinion that in mathematics the evidence proper to it was rejected, and logical evidence alone accepted; that everything in general which was not abstract knowledge was comprehended under the wide name of feeling, and consequently was little valued; and lastly that the Kantian ethics regarded the good will which immediately asserts itself upon knowledge of the circumstances, and guides to right and good action as mere feeling and emotion, and consequently as worthless and without merit, and would only recognise actions which proceed from abstract maxims as having moral worth.

The many-sided view of life as a whole which man, as distinguished from the lower animals, possesses through reason, may be compared to a geometrical, colourless, abstract, reduced plan of his actual life. He, therefore, stands to the lower animals as the navigator who, by means of chart, compass, and quadrant, knows accurately his course and his position at any time upon the sea, stands to the uneducated sailors who see only the waves and the heavens. Thus it is worth noticing, and indeed wonderful, how, besides his life in the concrete, man always lives another life in the abstract. In the former he is given as a prey to all the storms of actual life, and to the influence of the present; he must struggle, suffer, and die like the brute. But his life in the abstract, as it lies before his rational consciousness, is the still reflection of the former, and of the world in which he lives; it is just that reduced chart or plan to which we have referred. Here in the sphere of quiet deliberation, what completely possessed him and moved him intensely before, appears to him cold, colourless, and for the moment external to him; he is merely the spectator, the observer. In respect of this withdrawal into reflection he may be compared to an actor who has played his part in one scene, and who takes his place among the audience till it is time for him to go upon the stage again, and quietly looks on at whatever may happen, even though it be the preparation for his own death (in the piece), but afterwards he again goes on the stage and acts and suffers as he must. From this double life proceeds that quietness peculiar to human beings, so very different from the thoughtlessness of the brutes, and with which, in accordance with previous reflection, or a formed determination, or a recognised necessity, a man suffers or accomplishes in cold blood, what is of the utmost and often terrible importance to him; suicide, execution,

the duel, enterprises of every kind fraught with danger to life, and, in general, things against which his whole animal nature rebels. Under such circumstances we see to what an extent reason has mastered the animal nature, and we say to the strong: σιδηρειον νυ τοι ἠτορ! (*ferreum certe tibi cor*), Il. 24, 521. Here we can say truly that reason manifests itself practically, and thus wherever action is guided by reason, where the motives are abstract concepts, wherever we are not determined by particular ideas of perception, nor by the impression of the moment which guides the brutes, there *practical reason* shows itself. But I have fully explained in the Appendix, and illustrated by examples, that this is entirely different from and unrelated to the ethical worth of actions; that rational action and virtuous action are two entirely different things; that reason may just as well find itself in connection with great evil as with great good, and by its assistance may give great power to the one as well as to the other; that it is equally ready and valuable for the methodical and consistent carrying out of the noble and of the bad intention, of the wise as of the foolish maxim; which all results from the constitution of its nature, which is feminine, receptive, retentive, and not spontaneous; all this I have shown in detail in the Appendix, and illustrated by examples. What is said there would have been placed here, but on account of my polemic against Kant's pretended practical reason I have been obliged to relegate it to the Appendix, to which I therefore refer.

The ideal explained in the *Stoical philosophy* is the most complete development of *practical reason* in the true and genuine sense of the word; it is the highest summit to which man can attain by the mere use of his reason, and in it his difference from the brutes shows itself most distinctly. For the ethics of Stoicism are originally and essentially, not a doctrine of virtue, but merely a guide to a rational life, the end and aim of which is happiness through peace of mind. Virtuous conduct appears in it as it were merely by accident, as the means, not as the end. Therefore the ethical theory of Stoicism is in its whole nature and point of view fundamentally different from the ethical systems which lay stress directly upon virtue, such as the doctrines of the Vedas, of Plato, of Christianity, and of Kant. The aim of Stoical ethics is happiness: τελος το ευδαι μονειν (*virtutes omnes finem habere beatitudinem*) it is called in the account of the Stoa by Stobæus (Ecl., L. ii. c. 7, p. 114, and also p. 138). Yet the ethics of Stoicism teach that happiness can only be attained with certainty through inward peace and

quietness of spirit (αταραξια), and that this again can only be reached through virtue; this is the whole meaning of the saying that virtue is the highest good. But if indeed by degrees the end is lost sight of in the means, and virtue is inculcated in a way which discloses an interest entirely different from that of one's own happiness, for it contradicts this too distinctly; this is just one of those inconsistencies by means of which, in every system, the immediately known, or, as it is called, felt truth leads us back to the right way in defiance of syllogistic reasoning; as, for example, we see clearly in the ethical teaching of Spinoza, which deduces a pure doctrine of virtue from the egoistical *suum utile quærere* by means of palpable sophisms. According to this, as I conceive the spirit of the Stoical ethics, their source lies in the question whether the great prerogative of man, reason, which, by means of planned action and its results, relieves life and its burdens so much, might not also be capable of freeing him at once, directly, *i.e.*, through mere knowledge, completely, or nearly so, of the sorrows and miseries of every kind of which his life is full. They held that it was not in keeping with the prerogative of reason that the nature given with it, which by means of it comprehends and contemplates an infinity of things and circumstances, should yet, through the present, and the accidents that can be contained in the few years of a life that is short, fleeting, and uncertain, be exposed to such intense pain, to such great anxiety and suffering, as arise from the tempestuous strain of the desires and the antipathies; and they believed that the due application of reason must raise men above them, and can make them invulnerable. Therefore Antisthenes says: Δει κτασθαι νουν, η βροχον (*aut mentem parandam, aut laqueum.* Plut. de stoic. repugn., c. 14), *i.e.*, life is so full of troubles and vexations, that one must either rise above it by means of corrected thoughts, or leave it. It was seen that want and suffering did not directly and of necessity spring from not having, but from desiring to have and not having; that therefore this desire to have is the necessary condition under which alone it becomes a privation not to have and begets pain. Ου πενια λυπην εργαζεται, αλλα επιθυμια (*non paupertas dolorem efficit, sed cupiditas*), Epict., fragm. 25. Men learned also from experience that it is only the hope of what is claimed that begets and nourishes the wish; therefore neither the many unavoidable evils which are common to all, nor unattainable blessings, disquiet or trouble us, but only the trifling more or less of those things which we can avoid or attain; indeed, not only what is absolutely

unavoidable or unattainable, but also what is merely relatively so, leaves us quite undisturbed; therefore the ills that have once become joined to our individuality, or the good things that must of necessity always be denied us, are treated with indifference, in accordance with the peculiarity of human nature that every wish soon dies and can no more beget pain if it is not nourished by hope. It followed from all this that happiness always depends upon the proportion between our claims and what we receive. It is all one whether the quantities thus related be great or small, and the proportion can be established just as well by diminishing the amount of the first as by increasing the amount of the second; and in the same way it also follows that all suffering proceeds from the want of proportion between what we demand and expect and what we get. Now this want of proportion obviously lies only in knowledge, and it could be entirely abolished through fuller insight.[24] Therefore Chrysippus says: δει ζῃν κατ᾽ εμπειριαν των φυσει συμβαινοντων (Stob. Ecl., L. ii. c. 7, p. 134), that is, one ought to live with a due knowledge of the transitory nature of the things of the world. For as often as a man loses self-command, or is struck down by a misfortune, or grows angry, or becomes faint-hearted, he shows that he finds things different from what he expected, consequently that he was caught in error, and did not know the world and life, did not know that the will of the individual is crossed at every step by the chance of inanimate nature and the antagonism of aims and the wickedness of other individuals: he has therefore either not made use of his reason in order to arrive at a general knowledge of this characteristic of life, or he lacks judgment, in that he does not recognise in the particular what he knows in general, and is therefore surprised by it and loses his self-command.[25] Thus also every keen pleasure is an error and an illusion, for no attained wish can give lasting satisfaction; and, moreover, every possession and every happiness is but lent by chance for an uncertain time, and may therefore be demanded back the next hour. All pain rests on the passing away of such an illusion; thus both arise from defective knowledge; the wise man therefore holds himself equally aloof from joy and sorrow, and no event disturbs his αταραξια.

In accordance with this spirit and aim of the Stoa, Epictetus began and ended with the doctrine as the kernel of his philosophy, that we should consider well and distinguish what depends upon us and what does not, and therefore entirely avoid counting upon the latter, whereby we shall certainly remain free from all pain, sorrow, and anxiety. But that which alone is

dependent upon us is the will; and here a transition gradually takes place to a doctrine of virtue, for it is observed that as the outer world, which is independent of us, determines good and bad fortune, so inner contentment with ourselves, or the absence of it, proceeds from the will. But it was then asked whether we ought to apply the words *bonum* and *malum* to the two former or to the two latter? This was indeed arbitrary and a matter of choice, and did not make any real difference, but yet the Stoics disputed everlastingly with the Peripatetics and Epicureans about it, and amused themselves with the inadmissible comparison of two entirely incommensurable quantities, and the antithetical, paradoxical judgments which proceeded from them, and which they flung at each other. The *Paradoxa* of Cicero afford us an interesting collection of these from the Stoical side.

Zeno, the founder, seems originally to have followed a somewhat different path. The starting-point with him was that for the attainment of the highest good, *i.e.*, blessedness and spiritual peace, one must live in harmony with oneself (ὁμολογουμενους ξῃν; δ΄ εστι καθ΄ ἑνα λογον και συμφωνον ξῃν. — *Consonanter vivere: hoc est secundum unam rationem et concordem sibi vivere.* Stob. Ecl. eth. L. ii., c. 7, p. 132. Also: Αρετην διαθεσιν ειναι ψυχης συμφωνον ἑαυτῃ περι ὁλον τον βιον. *Virtutem esse animi affectiomem secum per totam vitam consentientem*, *ibid.*, p. 104.) Now this was only possible for a man if he determined himself entirely rationally, according to concepts, not according to changing impressions and moods; since, however, only the maxims of our conduct, not the consequences nor the outward circumstances, are in our power, in order to be always consistent we must set before us as our aim only the maxims and not the consequences and circumstances, and thus again a doctrine of virtue is introduced.

But the ethical principle of Zeno — to live in harmony with oneself — appeared even to his immediate successors to be too formal and empty. They therefore gave it material content by the addition— "to live in harmony with nature" (ὁμολογουμενως τῃ φυσει ζῃν), which, as Stobæus mentions in another place, was first added by Kleanthes, and extended the matter very much on account of the wide sphere of the concept and the vagueness of the expression. For Kleanthes meant the whole of nature in general, while Chrysippus meant human nature in particular (Diog. Laert., 7, 89). It followed that what alone was adapted to the latter was virtue, just as the satisfaction of animal desires was adapted to animal natures; and thus ethics had again to be forcibly united to a doctrine of virtue, and in some way or other established through physics. For the Stoics always aimed at unity of principle, as for them God and the world were not dissevered.

The ethical system of Stoicism, regarded as a whole, is in fact a very valuable and estimable attempt to use the great prerogative of man, reason, for an important and salutary end; to raise him above the suffering and pain to which all life is exposed, by means of a maxim —

"*Qua ratione queas traducere leniter œvum:*

Ne te semper inops agitet vexetque cupido,

Ne pavor et rerum mediocriter utilium spes,"

and thus to make him partake, in the highest degree, of the dignity which belongs to him as a rational being, as distinguished from the brutes; a

dignity of which, in this sense at any rate, we can speak, though not in any other. It is a consequence of my view of the ethical system of Stoicism that it must be explained at the part of my work at which I consider what reason is and what it can do. But although it may to a certain extent be possible to attain that end through the application of reason, and through a purely rational system of ethics, and although experience shows that the happiest men are those purely rational characters commonly called practical philosophers, — and rightly so, because just as the true, that is, the theoretical philosopher carries life into the concept, they carry the concept into life, — yet it is far from the case that perfection can be attained in this way, and that the reason, rightly used, can really free us from the burden and sorrow of life, and lead us to happiness. Rather, there lies an absolute contradiction in wishing to live without suffering, and this contradiction is also implied in the commonly used expression, "blessed life." This will become perfectly clear to whoever comprehends the whole of the following exposition. In this purely rational system of ethics the contradiction reveals itself thus, the Stoic is obliged in his doctrine of the way to the blessed life (for that is what his ethical system always remains) to insert a recommendation of suicide (as among the magnificent ornaments and apparel of Eastern despots there is always a costly vial of poison) for the case in which the sufferings of the body, which cannot be philosophised away by any principles or syllogistic reasonings, are paramount and incurable; thus its one aim, blessedness, is rendered vain, and nothing remains as a mode of escape from suffering except death; in such a case then death must be voluntarily accepted, just as we would take any other medicine. Here then a marked antagonism is brought out between the ethical system of Stoicism and all those systems referred to above which make virtue in itself directly, and accompanied by the most grievous sorrows, their aim, and will not allow a man to end his life in order to escape from suffering. Not one of them, however, was able to give the true reason for the rejection of suicide, but they laboriously collected illusory explanations from all sides: the true reason will appear in the Fourth Book in the course of the development of our system. But the antagonism referred to reveals and establishes the essential difference in fundamental principle between Stoicism, which is just a special form of endæmonism, and those doctrines we have mentioned, although both are often at one in their results, and are apparently related. And the inner contradiction referred to above,

with which the ethical system of Stoicism is affected even in its fundamental thought, shows itself further in the circumstance that its ideal, the Stoic philosopher, as the system itself represents him, could never obtain life or inner poetic truth, but remains a wooden, stiff lay-figure of which nothing can be made. He cannot himself make use of his wisdom, and his perfect peace, contentment, and blessedness directly contradict the nature of man, and preclude us from forming any concrete idea of him. When compared with him, how entirely different appear the overcomers of the world, and voluntary hermits that Indian philosophy presents to us, and has actually produced; or indeed, the holy man of Christianity, that excellent form full of deep life, of the greatest poetic truth, and the highest significance, which stands before us in perfect virtue, holiness, and sublimity, yet in a state of supreme suffering.[26]

Second Book. The World As Will.

First Aspect. The Objectification Of The Will.

Nos habitat, non tartara, sed nec sidera coeli:
Spiritus, in nobis qui viget, illa facit.

§ 17. In the first book we considered the idea merely as such, that is, only according to its general form. It is true that as far as the abstract idea, the concept, is concerned, we obtained a knowledge of it in respect of its content also, because it has content and meaning only in relation to the idea of perception, without which it would be worthless and empty. Accordingly, directing our attention exclusively to the idea of perception, we shall now endeavour to arrive at a knowledge of its content, its more exact definition, and the forms which it presents to us. And it will specially interest us to find an explanation of its peculiar significance, that significance which is otherwise merely felt, but on account of which it is that these pictures do not pass by us entirely strange and meaningless, as they must otherwise do, but speak to us directly, are understood, and obtain an interest which concerns our whole nature.

We direct our attention to mathematics, natural science, and philosophy, for each of these holds out the hope that it will afford us a part of the explanation we desire. Now, taking philosophy first, we find that it is like a monster with many heads, each of which speaks a different language. They are not, indeed, all at variance on the point we are here considering, the significance of the idea of perception. For, with the exception of the Sceptics and the Idealists, the others, for the most part, speak very much in the same way of an *object* which constitutes the *basis* of the idea, and which is indeed different in its whole being and nature from the idea, but yet is in all points as like it as one egg is to another. But this does not help us, for we are quite unable to distinguish such an object from the idea; we find that they are one and the same; for every object always and for ever presupposes a subject, and therefore remains idea, so that we recognised objectivity as belonging to the most universal form of the idea, which is the division into subject and object. Further, the principle of sufficient reason, which is referred to in support of this doctrine, is for us merely the form of the idea, the orderly combination of one idea with another, but not the combination of the whole finite or infinite series of ideas with something which is not idea at all, and which cannot therefore be presented in perception. Of the

Sceptics and Idealists we spoke above, in examining the controversy about the reality of the outer world.

If we turn to mathematics to look for the fuller knowledge we desire of the idea of perception, which we have, as yet, only understood generally, merely in its form, we find that mathematics only treats of these ideas so far as they fill time and space, that is, so far as they are quantities. It will tell us with the greatest accuracy the how-many and the how-much; but as this is always merely relative, that is to say, merely a comparison of one idea with others, and a comparison only in the one respect of quantity, this also is not the information we are principally in search of.

Lastly, if we turn to the wide province of natural science, which is divided into many fields, we may, in the first place, make a general division of it into two parts. It is either the description of forms, which I call *Morphology*, or the explanation of changes, which I call *Etiology*. The first treats of the permanent forms, the second of the changing matter, according to the laws of its transition from one form to another. The first is the whole extent of what is generally called natural history. It teaches us, especially in the sciences of botany and zoology, the various permanent, organised, and therefore definitely determined forms in the constant change of individuals; and these forms constitute a great part of the content of the idea of perception. In natural history they are classified, separated, united, arranged according to natural and artificial systems, and brought under concepts which make a general view and knowledge of the whole of them possible. Further, an infinitely fine analogy both in the whole and in the parts of these forms, and running through them all (*unité de plan*), is established, and thus they may be compared to innumerable variations on a theme which is not given. The passage of matter into these forms, that is to say, the origin of individuals, is not a special part of natural science, for every individual springs from its like by generation, which is everywhere equally mysterious, and has as yet evaded definite knowledge. The little that is known on the subject finds its place in physiology, which belongs to that part of natural science I have called etiology. Mineralogy also, especially where it becomes geology, inclines towards etiology, though it principally belongs to morphology. Etiology proper comprehends all those branches of natural science in which the chief concern is the knowledge of cause and effect. The sciences teach how, according to an invariable rule, one condition of matter is necessarily followed by a certain other condition;

how one change necessarily conditions and brings about a certain other change; this sort of teaching is called *explanation*. The principal sciences in this department are mechanics, physics, chemistry, and physiology.

If, however, we surrender ourselves to its teaching, we soon become convinced that etiology cannot afford us the information we chiefly desire, any more than morphology. The latter presents to us innumerable and infinitely varied forms, which are yet related by an unmistakable family likeness. These are for us ideas, and when only treated in this way, they remain always strange to us, and stand before us like hieroglyphics which we do not understand. Etiology, on the other hand, teaches us that, according to the law of cause and effect, this particular condition of matter brings about that other particular condition, and thus it has explained it and performed its part. However, it really does nothing more than indicate the orderly arrangement according to which the states of matter appear in space and time, and teach in all cases what phenomenon must necessarily appear at a particular time in a particular place. It thus determines the position of phenomena in time and space, according to a law whose special content is derived from experience, but whose universal form and necessity is yet known to us independently of experience. But it affords us absolutely no information about the inner nature of any one of these phenomena: this is called a *force of nature*, and it lies outside the province of causal explanation, which calls the constant uniformity with which manifestations of such a force appear whenever their known conditions are present, a *law of nature*. But this law of nature, these conditions, and this appearance in a particular place at a particular time, are all that it knows or ever can know. The force itself which manifests itself, the inner nature of the phenomena which appear in accordance with these laws, remains always a secret to it, something entirely strange and unknown in the case of the simplest as well as of the most complex phenomena. For although as yet etiology has most completely achieved its aim in mechanics, and least completely in physiology, still the force on account of which a stone falls to the ground or one body repels another is, in its inner nature, not less strange and mysterious than that which produces the movements and the growth of an animal. The science of mechanics presupposes matter, weight, impenetrability, the possibility of communicating motion by impact, inertia and so forth as ultimate facts, calls them forces of nature, and their necessary and orderly appearance under certain conditions a law of nature.

Only after this does its explanation begin, and it consists in indicating truly and with mathematical exactness, how, where and when each force manifests itself, and in referring every phenomenon which presents itself to the operation of one of these forces. Physics, chemistry, and physiology proceed in the same way in their province, only they presuppose more and accomplish less. Consequently the most complete etiological explanation of the whole of nature can never be more than an enumeration of forces which cannot be explained, and a reliable statement of the rule according to which phenomena appear in time and space, succeed, and make way for each other. But the inner nature of the forces which thus appear remains unexplained by such an explanation, which must confine itself to phenomena and their arrangement, because the law which it follows does not extend further. In this respect it may be compared to a section of a piece of marble which shows many veins beside each other, but does not allow us to trace the course of the veins from the interior of the marble to its surface. Or, if I may use an absurd but more striking comparison, the philosophical investigator must always have the same feeling towards the complete etiology of the whole of nature, as a man who, without knowing how, has been brought into a company quite unknown to him, each member of which in turn presents another to him as his friend and cousin, and therefore as quite well known, and yet the man himself, while at each introduction he expresses himself gratified, has always the question on his lips: "But how the deuce do I stand to the whole company?"

Thus we see that, with regard to those phenomena which we know only as our ideas, etiology can never give us the desired information that shall carry us beyond this point. For, after all its explanations, they still remain quite strange to us, as mere ideas whose significance we do not understand. The causal connection merely gives us the rule and the relative order of their appearance in space and time, but affords us no further knowledge of that which so appears. Moreover, the law of causality itself has only validity for ideas, for objects of a definite class, and it has meaning only in so far as it presupposes them. Thus, like these objects themselves, it always exists only in relation to a subject, that is, conditionally; and so it is known just as well if we start from the subject, *i.e.*, *a priori*, as if we start from the object, *i.e.*, *a posteriori*. Kant indeed has taught us this.

But what now impels us to inquiry is just that we are not satisfied with knowing that we have ideas, that they are such and such, and that they are

connected according to certain laws, the general expression of which is the principle of sufficient reason. We wish to know the significance of these ideas; we ask whether this world is merely idea; in which case it would pass by us like an empty dream or a baseless vision, not worth our notice; or whether it is also something else, something more than idea, and if so, what. Thus much is certain, that this something we seek for must be completely and in its whole nature different from the idea; that the forms and laws of the idea must therefore be completely foreign to it; further, that we cannot arrive at it from the idea under the guidance of the laws which merely combine objects, ideas, among themselves, and which are the forms of the principle of sufficient reason.

Thus we see already that we can never arrive at the real nature of things from without. However much we investigate, we can never reach anything but images and names. We are like a man who goes round a castle seeking in vain for an entrance, and sometimes sketching the façades. And yet this is the method that has been followed by all philosophers before me.

§ 18. In fact, the meaning for which we seek of that world which is present to us only as our idea, or the transition from the world as mere idea of the knowing subject to whatever it may be besides this, would never be found if the investigator himself were nothing more than the pure knowing subject (a winged cherub without a body). But he is himself rooted in that world; he finds himself in it as an *individual*, that is to say, his knowledge, which is the necessary supporter of the whole world as idea, is yet always given through the medium of a body, whose affections are, as we have shown, the starting-point for the understanding in the perception of that world. His body is, for the pure knowing subject, an idea like every other idea, an object among objects. Its movements and actions are so far known to him in precisely the same way as the changes of all other perceived objects, and would be just as strange and incomprehensible to him if their meaning were not explained for him in an entirely different way. Otherwise he would see his actions follow upon given motives with the constancy of a law of nature, just as the changes of other objects follow upon causes, stimuli, or motives. But he would not understand the influence of the motives any more than the connection between every other effect which he sees and its cause. He would then call the inner nature of these manifestations and actions of his body which he did not understand a force, a quality, or a character, as he pleased, but he would have no further insight

into it. But all this is not the case; indeed the answer to the riddle is given to the subject of knowledge who appears as an individual, and the answer is *will*. This and this alone gives him the key to his own existence, reveals to him the significance, shows him the inner mechanism of his being, of his action, of his movements. The body is given in two entirely different ways to the subject of knowledge, who becomes an individual only through his identity with it. It is given as an idea in intelligent perception, as an object among objects and subject to the laws of objects. And it is also given in quite a different way as that which is immediately known to every one, and is signified by the word *will*. Every true act of his will is also at once and without exception a movement of his body. The act of will and the movement of the body are not two different things objectively known, which the bond of causality unites; they do not stand in the relation of cause and effect; they are one and the same, but they are given in entirely different ways, — immediately, and again in perception for the understanding. The action of the body is nothing but the act of the will objectified, *i.e.*, passed into perception. It will appear later that this is true of every movement of the body, not merely those which follow upon motives, but also involuntary movements which follow upon mere stimuli, and, indeed, that the whole body is nothing but objectified will, *i.e.*, will become idea. All this will be proved and made quite clear in the course of this work. In one respect, therefore, I shall call the body the *objectivity of will*; as in the previous book, and in the essay on the principle of sufficient reason, in accordance with the one-sided point of view intentionally adopted there (that of the idea), I called it *the immediate object*. Thus in a certain sense we may also say that will is the knowledge *a priori* of the body, and the body is the knowledge *a posteriori* of the will. Resolutions of the will which relate to the future are merely deliberations of the reason about what we shall will at a particular time, not real acts of will. Only the carrying out of the resolve stamps it as will, for till then it is never more than an intention that may be changed, and that exists only in the reason *in abstracto*. It is only in reflection that to will and to act are different; in reality they are one. Every true, genuine, immediate act of will is also, at once and immediately, a visible act of the body. And, corresponding to this, every impression upon the body is also, on the other hand, at once and immediately an impression upon the will. As such it is called pain when it is opposed to the will; gratification or pleasure when it is in accordance with it. The degrees of

both are widely different. It is quite wrong, however, to call pain and pleasure ideas, for they are by no means ideas, but immediate affections of the will in its manifestation, the body; compulsory, instantaneous willing or not-willing of the impression which the body sustains. There are only a few impressions of the body which do not touch the will, and it is through these alone that the body is an immediate object of knowledge, for, as perceived by the understanding, it is already an indirect object like all others. These impressions are, therefore, to be treated directly as mere ideas, and excepted from what has been said. The impressions we refer to are the affections of the purely objective senses of sight, hearing, and touch, though only so far as these organs are affected in the way which is specially peculiar to their specific nature. This affection of them is so excessively weak an excitement of the heightened and specifically modified sensibility of these parts that it does not affect the will, but only furnishes the understanding with the data out of which the perception arises, undisturbed by any excitement of the will. But every stronger or different kind of affection of these organs of sense is painful, that is to say, against the will, and thus they also belong to its objectivity. Weakness of the nerves shows itself in this, that the impressions which have only such a degree of strength as would usually be sufficient to make them data for the understanding reach the higher degree at which they influence the will, that is to say, give pain or pleasure, though more often pain, which is, however, to some extent deadened and inarticulate, so that not only particular tones and strong light are painful to us, but there ensues a generally unhealthy and hypochondriacal disposition which is not distinctly understood. The identity of the body and the will shows itself further, among other ways, in the circumstance that every vehement and excessive movement of the will, *i.e.*, every emotion, agitates the body and its inner constitution directly, and disturbs the course of its vital functions. This is shown in detail in "Will in Nature," p. 27 of the second edition and p. 28 of the third.

Lastly, the knowledge which I have of my will, though it is immediate, cannot be separated from that which I have of my body. I know my will, not as a whole, not as a unity, not completely, according to its nature, but I know it only in its particular acts, and therefore in time, which is the form of the phenomenal aspect of my body, as of every object. Therefore the body is a condition of the knowledge of my will. Thus, I cannot really imagine this will apart from my body. In the essay on the principle of

sufficient reason, the will, or rather the subject of willing, is treated as a special class of ideas or objects. But even there we saw this object become one with the subject; that is, we saw it cease to be an object. We there called this union the miracle κατ᾽ εξοχην, and the whole of the present work is to a certain extent an explanation of this. So far as I know my will specially as object, I know it as body. But then I am again at the first class of ideas laid down in that essay, *i.e.*, real objects. As we proceed we shall see always more clearly that these ideas of the first class obtain their explanation and solution from those of the fourth class given in the essay, which could no longer be properly opposed to the subject as object, and that, therefore, we must learn to understand the inner nature of the law of causality which is valid in the first class, and of all that happens in accordance with it from the law of motivation which governs the fourth class.

The identity of the will and the body, of which we have now given a cursory explanation, can only be proved in the manner we have adopted here. We have proved this identity for the first time, and shall do so more and more fully in the course of this work. By "proved" we mean raised from the immediate consciousness, from knowledge in the concrete to abstract knowledge of the reason, or carried over into abstract knowledge. On the other hand, from its very nature it can never be demonstrated, that is, deduced as indirect knowledge from some other more direct knowledge, just because it is itself the most direct knowledge; and if we do not apprehend it and stick to it as such, we shall expect in vain to receive it again in some indirect way as derivative knowledge. It is knowledge of quite a special kind, whose truth cannot therefore properly be brought under any of the four rubrics under which I have classified all truth in the essay on the principle of sufficient reason, § 29, the logical, the empirical, the metaphysical, and the metalogical, for it is not, like all these, the relation of an abstract idea to another idea, or to the necessary form of perceptive or of abstract ideation, but it is the relation of a judgment to the connection which an idea of perception, the body, has to that which is not an idea at all, but something *toto genere* different, will. I should like therefore to distinguish this from all other truth, and call it κατ᾽ εξοχην *philosophical truth*. We can turn the expression of this truth in different ways and say: My body and my will are one; — or, What as an idea of perception I call my body, I call my will, so far as I am conscious of it in an entirely different way which cannot be compared to any other; — or, My body is the *objectivity* of my will; —

or, My body considered apart from the fact that it is my idea is still my will, and so forth.[27]

§ 19. In the first book we were reluctantly driven to explain the human body as merely idea of the subject which knows it, like all the other objects of this world of perception. But it has now become clear that what enables us consciously to distinguish our own body from all other objects which in other respects are precisely the same, is that our body appears in consciousness in quite another way *toto genere* different from idea, and this we denote by the word *will*; and that it is just this double knowledge which we have of our own body that affords us information about it, about its action and movement following on motives, and also about what it experiences by means of external impressions; in a word, about what it is, not as idea, but as more than idea; that is to say, what it is *in itself*. None of this information have we got directly with regard to the nature, action, and experience of other real objects.

It is just because of this special relation to one body that the knowing subject is an individual. For regarded apart from this relation, his body is for him only an idea like all other ideas. But the relation through which the knowing subject is an *individual*, is just on that account a relation which subsists only between him and one particular idea of all those which he has. Therefore he is conscious of this *one* idea, not merely as an idea, but in quite a different way as a will. If, however, he abstracts from that special relation, from that twofold and completely heterogeneous knowledge of what is one and the same, then that *one*, the body, is an idea like all other ideas. Therefore, in order to understand the matter, the individual who knows must either assume that what distinguishes that one idea from others is merely the fact that his knowledge stands in this double relation to it alone; that insight in two ways at the same time is open to him only in the case of this one object of perception, and that this is to be explained not by the difference of this object from all others, but only by the difference between the relation of his knowledge to this one object, and its relation to all other objects. Or else he must assume that this object is essentially different from all others; that it alone of all objects is at once both will and idea, while the rest are only ideas, *i.e.*, only phantoms. Thus he must assume that his body is the only real individual in the world, *i.e.*, the only phenomenon of will and the only immediate object of the subject. That other objects, considered merely as *ideas*, are like his body, that is, like it,

fill space (which itself can only be present as idea), and also, like it, are causally active in space, is indeed demonstrably certain from the law of causality which is *a priori* valid for ideas, and which admits of no effect without a cause; but apart from the fact that we can only reason from an effect to a cause generally, and not to a similar cause, we are still in the sphere of mere ideas, in which alone the law of causality is valid, and beyond which it can never take us. But whether the objects known to the individual only as ideas are yet, like his own body, manifestations of a will, is, as was said in the First Book, the proper meaning of the question as to the reality of the external world. To deny this is *theoretical egoism*, which on that account regards all phenomena that are outside its own will as phantoms, just as in a practical reference exactly the same thing is done by practical egoism. For in it a man regards and treats himself alone as a person, and all other persons as mere phantoms. Theoretical egoism can never be demonstrably refuted, yet in philosophy it has never been used otherwise than as a sceptical sophism, *i.e.*, a pretence. As a serious conviction, on the other hand, it could only be found in a madhouse, and as such it stands in need of a cure rather than a refutation. We do not therefore combat it any further in this regard, but treat it as merely the last stronghold of scepticism, which is always polemical. Thus our knowledge, which is always bound to individuality and is limited by this circumstance, brings with it the necessity that each of us can only *be one*, while, on the other hand, each of us can *know all*; and it is this limitation that creates the need for philosophy. We therefore who, for this very reason, are striving to extend the limits of our knowledge through philosophy, will treat this sceptical argument of theoretical egoism which meets us, as an army would treat a small frontier fortress. The fortress cannot indeed be taken, but the garrison can never sally forth from it, and therefore we pass it by without danger, and are not afraid to have it in our rear.

The double knowledge which each of us has of the nature and activity of his own body, and which is given in two completely different ways, has now been clearly brought out. We shall accordingly make further use of it as a key to the nature of every phenomenon in nature, and shall judge of all objects which are not our own bodies, and are consequently not given to our consciousness in a double way but only as ideas, according to the analogy of our own bodies, and shall therefore assume that as in one aspect they are idea, just like our bodies, and in this respect are analogous to them, so in

another aspect, what remains of objects when we set aside their existence as idea of the subject, must in its inner nature be the same as that in us which we call *will*. For what other kind of existence or reality should we attribute to the rest of the material world? Whence should we take the elements out of which we construct such a world? Besides will and idea nothing is known to us or thinkable. If we wish to attribute the greatest known reality to the material world which exists immediately only in our idea, we give it the reality which our own body has for each of us; for that is the most real thing for every one. But if we now analyse the reality of this body and its actions, beyond the fact that it is idea, we find nothing in it except the will; with this its reality is exhausted. Therefore we can nowhere find another kind of reality which we can attribute to the material world. Thus if we hold that the material world is something more than merely our idea, we must say that besides being idea, that is, in itself and according to its inmost nature, it is that which we find immediately in ourselves as *will*. I say according to its inmost nature; but we must first come to know more accurately this real nature of the will, in order that we may be able to distinguish from it what does not belong to itself, but to its manifestation, which has many grades. Such, for example, is the circumstance of its being accompanied by knowledge, and the determination by motives which is conditioned by this knowledge. As we shall see farther on, this does not belong to the real nature of will, but merely to its distinct manifestation as an animal or a human being. If, therefore, I say, — the force which attracts a stone to the earth is according to its nature, in itself, and apart from all idea, will, I shall not be supposed to express in this proposition the insane opinion that the stone moves itself in accordance with a known motive, merely because this is the way in which will appears in man.[28] We shall now proceed more clearly and in detail to prove, establish, and develop to its full extent what as yet has only been provisionally and generally explained.[29]

§ 20. As we have said, the will proclaims itself primarily in the voluntary movements of our own body, as the inmost nature of this body, as that which it is besides being object of perception, idea. For these voluntary movements are nothing else than the visible aspect of the individual acts of will, with which they are directly coincident and identical, and only distinguished through the form of knowledge into which they have passed, and in which alone they can be known, the form of idea.

But these acts of will have always a ground or reason outside themselves in motives. Yet these motives never determine more than what I will at *this* time, in *this* place, and under *these* circumstances, not *that* I will in general, or *what* I will in general, that is, the maxims which characterise my volition generally. Therefore the inner nature of my volition cannot be explained from these motives; but they merely determine its manifestation at a given point of time: they are merely the occasion of my will showing itself; but the will itself lies outside the province of the law of motivation, which determines nothing but its appearance at each point of time. It is only under the presupposition of my empirical character that the motive is a sufficient ground of explanation of my action. But if I abstract from my character, and then ask, why, in general, I will this and not that, no answer is possible, because it is only the manifestation of the will that is subject to the principle of sufficient reason, and not the will itself, which in this respect is to be called *groundless*. At this point I presuppose Kant's doctrine of the empirical and intelligible character, and also my own treatment of the subject in "The Fundamental Problems of Ethics," pp. 48, 58, and 178, *et seq.*, of first edition (p. 174, *et seq.*, of second edition). I shall also have to speak more fully on the question in the Fourth Book. For the present, I have only to draw attention to this, that the fact of one manifestation being established through another, as here the deed through the motive, does not at all conflict with the fact that its real nature is will, which itself has no *ground*; for as the principle of sufficient reason in all its aspects is only the form of knowledge, its validity extends only to the idea, to the phenomena, to the visibility of the will, but not to the will itself, which becomes visible.

If now every action of my body is the manifestation of an act of will in which my will itself in general, and as a whole, thus my character, expresses itself under given motives, manifestation of the will must be the inevitable condition and presupposition of every action. For the fact of its manifestation cannot depend upon something which does not exist directly and only through it, which consequently is for it merely accidental, and through which its manifestation itself would be merely accidental. Now that condition is just the whole body itself. Thus the body itself must be manifestation of the will, and it must be related to my will as a whole, that is, to my intelligible character, whose phenomenal appearance in time is my empirical character, as the particular action of the body is related to the particular act of the will. The whole body, then, must be simply my will

become visible, must be my will itself, so far as this is object of perception, an idea of the first class. It has already been advanced in confirmation of this that every impression upon my body also affects my will at once and immediately, and in this respect is called pain or pleasure, or, in its lower degrees, agreeable or disagreeable sensation; and also, conversely, that every violent movement of the will, every emotion or passion, convulses the body and disturbs the course of its functions. Indeed we can also give an etiological account, though a very incomplete one, of the origin of my body, and a somewhat better account of its development and conservation, and this is the substance of physiology. But physiology merely explains its theme in precisely the same way as motives explain action. Thus the physiological explanation of the functions of the body detracts just as little from the philosophical truth that the whole existence of this body and the sum total of its functions are merely the objectification of that will which appears in its outward actions in accordance with a motive, as the establishment of the individual action through the motive and the necessary sequence of the action from the motive conflicts with the fact that action in general, and according to its nature, is only the manifestation of a will which itself has no ground. If, however, physiology tries to refer even these outward actions, the immediate voluntary movements, to causes in the organism, — for example, if it explains the movement of the muscles as resulting from the presence of fluids ("like the contraction of a cord when it is wet," says Reil in his "Archiv für Physiologie," vol. vi. p. 153), even supposing it really could give a thorough explanation of this kind, yet this would never invalidate the immediately certain truth that every voluntary motion (*functiones animales*) is the manifestation of an act of will. Now, just as little can the physiological explanation of vegetative life (*functiones naturales vitales*), however far it may advance, ever invalidate the truth that the whole animal life which thus develops itself is the manifestation of will. In general, then, as we have shown above, no etiological explanation can ever give us more than the necessarily determined position in time and space of a particular manifestation, its necessary appearance there, according to a fixed law; but the inner nature of everything that appears in this way remains wholly inexplicable, and is presupposed by every etiological explanation, and merely indicated by the names, force, or law of nature, or, if we are speaking of action, character or will. Thus, although every particular action, under the presupposition of the definite character,

necessarily follows from the given motive, and although growth, the process of nourishment, and all the changes of the animal body take place according to necessarily acting causes (stimuli), yet the whole series of actions, and consequently every individual act, and also its condition, the whole body itself which accomplishes it, and therefore also the process through which and in which it exists, are nothing but the manifestation of the will, the becoming visible, *the objectification of the will*. Upon this rests the perfect suitableness of the human and animal body to the human and animal will in general, resembling, though far surpassing, the correspondence between an instrument made for a purpose and the will of the maker, and on this account appearing as design, *i.e.*, the teleological explanation of the body. The parts of the body must, therefore, completely correspond to the principal desires through which the will manifests itself; they must be the visible expression of these desires. Teeth, throat, and bowels are objectified hunger; the organs of generation are objectified sexual desire; the grasping hand, the hurrying feet, correspond to the more indirect desires of the will which they express. As the human form generally corresponds to the human will generally, so the individual bodily structure corresponds to the individually modified will, the character of the individual, and therefore it is throughout and in all its parts characteristic and full of expression. It is very remarkable that Parmenides already gave expression to this in the following verses, quoted by Aristotle (Metaph. iii. 5): —

Ὀς γαρ ἑκαστος εχει κρασιν μελεων πολυκαμπτων
Τως νοος ανθρωποισι παρεστηκεν; το γαρ αυτο
Εστιν, ὁπερ φρονεει, μελεων φυσις ανθρωποισι
Και πασιν και παντι; το γαρ πλεον εστι νοημα.

(Ut enim cuique complexio membrorum flexibilium se habet, ita mens hominibus adest: idem namque est, quod sapit, membrorum natura hominibus, et omnibus et omni: quod enim plus est, intelligentia est.)[30]

§ 21. Whoever has now gained from all these expositions a knowledge *in abstracto*, and therefore clear and certain, of what every one knows directly *in concreto*, *i.e.*, as feeling, a knowledge that his will is the real inner nature of his phenomenal being, which manifests itself to him as idea, both in his actions and in their permanent substratum, his body, and that his will is that which is most immediate in his consciousness, though it has not as such completely passed into the form of idea in which object and subject stand

over against each other, but makes itself known to him in a direct manner, in which he does not quite clearly distinguish subject and object, yet is not known as a whole to the individual himself, but only in its particular acts, — whoever, I say, has with me gained this conviction will find that of itself it affords him the key to the knowledge of the inmost being of the whole of nature; for he now transfers it to all those phenomena which are not given to him, like his own phenomenal existence, both in direct and indirect knowledge, but only in the latter, thus merely one-sidedly as *idea* alone. He will recognise this will of which we are speaking not only in those phenomenal existences which exactly resemble his own, in men and animals as their inmost nature, but the course of reflection will lead him to recognise the force which germinates and vegetates in the plant, and indeed the force through which the crystal is formed, that by which the magnet turns to the north pole, the force whose shock he experiences from the contact of two different kinds of metals, the force which appears in the elective affinities of matter as repulsion and attraction, decomposition and combination, and, lastly, even gravitation, which acts so powerfully throughout matter, draws the stone to the earth and the earth to the sun, — all these, I say, he will recognise as different only in their phenomenal existence, but in their inner nature as identical, as that which is directly known to him so intimately and so much better than anything else, and which in its most distinct manifestation is called *will*. It is this application of reflection alone that prevents us from remaining any longer at the phenomenon, and leads us to the *thing in itself*. Phenomenal existence is idea and nothing more. All idea, of whatever kind it may be, all *object*, is *phenomenal* existence, but the *will* alone is a *thing in itself*. As such, it is throughout not idea, but *toto genere* different from it; it is that of which all idea, all object, is the phenomenal appearance, the visibility, the objectification. It is the inmost nature, the kernel, of every particular thing, and also of the whole. It appears in every blind force of nature and also in the preconsidered action of man; and the great difference between these two is merely in the degree of the manifestation, not in the nature of what manifests itself.

§ 22. Now, if we are to think as an object this thing-in-itself (we wish to retain the Kantian expression as a standing formula), which, as such, is never object, because all object is its mere manifestation, and therefore cannot be it itself, we must borrow for it the name and concept of an object,

of something in some way objectively given, consequently of one of its own manifestations. But in order to serve as a clue for the understanding, this can be no other than the most complete of all its manifestations, *i.e.*, the most distinct, the most developed, and directly enlightened by knowledge. Now this is the human will. It is, however, well to observe that here, at any rate, we only make use of a *denominatio a potiori*, through which, therefore, the concept of will receives a greater extension than it has hitherto had. Knowledge of the identical in different phenomena, and of difference in similar phenomena, is, as Plato so often remarks, a *sine qua non* of philosophy. But hitherto it was not recognised that every kind of active and operating force in nature is essentially identical with will, and therefore the multifarious kinds of phenomena were not seen to be merely different species of the same genus, but were treated as heterogeneous. Consequently there could be no word to denote the concept of this genus. I therefore name the genus after its most important species, the direct knowledge of which lies nearer to us and guides us to the indirect knowledge of all other species. But whoever is incapable of carrying out the required extension of the concept will remain involved in a permanent misunderstanding. For by the word *will* he understands only that species of it which has hitherto been exclusively denoted by it, the will which is guided by knowledge, and whose manifestation follows only upon motives, and indeed merely abstract motives, and thus takes place under the guidance of the reason. This, we have said, is only the most prominent example of the manifestation of will. We must now distinctly separate in thought the inmost essence of this manifestation which is known to us directly, and then transfer it to all the weaker, less distinct manifestations of the same nature, and thus we shall accomplish the desired extension of the concept of will. From another point of view I should be equally misunderstood by any one who should think that it is all the same in the end whether we denote this inner nature of all phenomena by the word *will* or by any other. This would be the case if the thing-in-itself were something whose existence we merely *inferred*, and thus knew indirectly and only in the abstract. Then, indeed, we might call it what we pleased; the name would stand merely as the symbol of an unknown quantity. But the word *will*, which, like a magic spell, discloses to us the inmost being of everything in nature, is by no means an unknown quantity, something arrived at only by inference, but is fully and immediately comprehended, and is so familiar to us that we know and

understand what will is far better than anything else whatever. The concept of will has hitherto commonly been subordinated to that of force, but I reverse the matter entirely, and desire that every force in nature should be thought as will. It must not be supposed that this is mere verbal quibbling or of no consequence; rather, it is of the greatest significance and importance. For at the foundation of the concept of force, as of all other concepts, there ultimately lies the knowledge in sense-perception of the objective world, that is to say, the phenomenon, the idea; and the concept is constructed out of this. It is an abstraction from the province in which cause and effect reign, *i.e.*, from ideas of perception, and means just the causal nature of causes at the point at which this causal nature is no further etiologically explicable, but is the necessary presupposition of all etiological explanation. The concept will, on the other hand, is of all possible concepts the only one which has its source *not* in the phenomenal, *not* in the mere idea of perception, but comes from within, and proceeds from the most immediate consciousness of each of us, in which each of us knows his own individuality, according to its nature, immediately, apart from all form, even that of subject and object, and which at the same time is this individuality, for here the subject and the object of knowledge are one. If, therefore, we refer the concept of *force* to that of *will*, we have in fact referred the less known to what is infinitely better known; indeed, to the one thing that is really immediately and fully known to us, and have very greatly extended our knowledge. If, on the contrary, we subsume the concept of will under that of force, as has hitherto always been done, we renounce the only immediate knowledge which we have of the inner nature of the world, for we allow it to disappear in a concept which is abstracted from the phenomenal, and with which we can therefore never go beyond the phenomenal.

§ 23. The *will* as a thing in itself is quite different from its phenomenal appearance, and entirely free from all the forms of the phenomenal, into which it first passes when it manifests itself, and which therefore only concern its *objectivity*, and are foreign to the will itself. Even the most universal form of all idea, that of being object for a subject, does not concern it; still less the forms which are subordinate to this and which collectively have their common expression in the principle of sufficient reason, to which we know that time and space belong, and consequently multiplicity also, which exists and is possible only through these. In this last

regard I shall call time and space the *principium individuationis*, borrowing an expression from the old schoolmen, and I beg to draw attention to this, once for all. For it is only through the medium of time and space that what is one and the same, both according to its nature and to its concept, yet appears as different, as a multiplicity of co-existent and successive phenomena. Thus time and space are the *principium individuationis*, the subject of so many subtleties and disputes among the schoolmen, which may be found collected in Suarez (Disp. 5, Sect. 3). According to what has been said, the will as a thing-in-itself lies outside the province of the principle of sufficient reason in all its forms, and is consequently completely groundless, although all its manifestations are entirely subordinated to the principle of sufficient reason. Further, it is free from all *multiplicity*, although its manifestations in time and space are innumerable. It is itself one, though not in the sense in which an object is one, for the unity of an object can only be known in opposition to a possible multiplicity; nor yet in the sense in which a concept is one, for the unity of a concept originates only in abstraction from a multiplicity; but it is one as that which lies outside time and space, the *principium individuationis*, *i.e.*, the possibility of multiplicity. Only when all this has become quite clear to us through the subsequent examination of the phenomena and different manifestations of the will, shall we fully understand the meaning of the Kantian doctrine that time, space and causality do not belong to the thing-in-itself, but are only forms of knowing.

The uncaused nature of will has been actually recognised, where it manifests itself most distinctly, as the will of man, and this has been called free, independent. But on account of the uncaused nature of the will itself, the necessity to which its manifestation is everywhere subjected has been overlooked, and actions are treated as free, which they are not. For every individual action follows with strict necessity from the effect of the motive upon the character. All necessity is, as we have already said, the relation of the consequent to the reason, and nothing more. The principle of sufficient reason is the universal form of all phenomena, and man in his action must be subordinated to it like every other phenomenon. But because in self-consciousness the will is known directly and in itself, in this consciousness lies also the consciousness of freedom. The fact is, however, overlooked that the individual, the person, is not will as a thing-in-itself, but is a *phenomenon* of will, is already determined as such, and has come under the

form of the phenomenal, the principle of sufficient reason. Hence arises the strange fact that every one believes himself *a priori* to be perfectly free, even in his individual actions, and thinks that at every moment he can commence another manner of life, which just means that he can become another person. But *a posteriori*, through experience, he finds to his astonishment that he is not free, but subjected to necessity; that in spite of all his resolutions and reflections he does not change his conduct, and that from the beginning of his life to the end of it, he must carry out the very character which he himself condemns, and as it were play the part he has undertaken to the end. I cannot pursue this subject further at present, for it belongs, as ethical, to another part of this work. In the meantime, I only wish to point out here that the *phenomenon* of the will which in itself is uncaused, is yet as such subordinated to the law of necessity, that is, the principle of sufficient reason, so that in the necessity with which the phenomena of nature follow each other, we may find nothing to hinder us from recognising in them the manifestations of will.

Only those changes which have no other ground than a motive, *i.e.*, an idea, have hitherto been regarded as manifestations of will. Therefore in nature a will has only been attributed to man, or at the most to animals; for knowledge, the idea, is of course, as I have said elsewhere, the true and exclusive characteristic of animal life. But that the will is also active where no knowledge guides it, we see at once in the instinct and the mechanical skill of animals.[31] That they have ideas and knowledge is here not to the point, for the end towards which they strive as definitely as if it were a known motive, is yet entirely unknown to them. Therefore in such cases their action takes place without motive, is not guided by the idea, and shows us first and most distinctly how the will may be active entirely without knowledge. The bird of a year old has no idea of the eggs for which it builds a nest; the young spider has no idea of the prey for which it spins a web; nor has the ant-lion any idea of the ants for which he digs a trench for the first time. The larva of the stag-beetle makes the hole in the wood, in which it is to await its metamorphosis, twice as big if it is going to be a male beetle as if it is going to be a female, so that if it is a male there may be room for the horns, of which, however, it has no idea. In such actions of these creatures the will is clearly operative as in their other actions, but it is in blind activity, which is indeed accompanied by knowledge but not guided by it. If now we have once gained insight into the fact, that idea as motive is

not a necessary and essential condition of the activity of the will, we shall more easily recognise the activity of will where it is less apparent. For example, we shall see that the house of the snail is no more made by a will which is foreign to the snail itself, than the house which we build is produced through another will than our own; but we shall recognise in both houses the work of a will which objectifies itself in both the phenomena — a will which works in us according to motives, but in the snail still blindly as formative impulse directed outwards. In us also the same will is in many ways only blindly active: in all the functions of our body which are not guided by knowledge, in all its vital and vegetative processes, digestion, circulation, secretion, growth, reproduction. Not only the actions of the body, but the whole body itself is, as we have shown above, phenomenon of the will, objectified will, concrete will. All that goes on in it must therefore proceed through will, although here this will is not guided by knowledge, but acts blindly according to causes, which in this case are called *stimuli*.

I call a *cause*, in the narrowest sense of the word, that state of matter, which, while it introduces another state with necessity, yet suffers just as great a change itself as that which it causes; which is expressed in the rule, "action and reaction are equal." Further, in the case of what is properly speaking a cause, the effect increases directly in proportion to the cause, and therefore also the reaction. So that, if once the mode of operation be known, the degree of the effect may be measured and calculated from the degree of the intensity of the cause; and conversely the degree of the intensity of the cause may be calculated from the degree of the effect. Such causes, properly so called, operate in all the phenomena of mechanics, chemistry, and so forth; in short, in all the changes of unorganised bodies. On the other hand, I call a *stimulus*, such a cause as sustains no reaction proportional to its effect, and the intensity of which does not vary directly in proportion to the intensity of its effect, so that the effect cannot be measured by it. On the contrary, a small increase of the stimulus may cause a very great increase of the effect, or conversely, it may eliminate the previous effect altogether, and so forth. All effects upon organised bodies as such are of this kind. All properly organic and vegetative changes of the animal body must therefore be referred to stimuli, not to mere causes. But the stimulus, like every cause and motive generally, never determines more than the point of time and space at which the manifestation of every force is to take place, and does not determine the inner nature of the force itself which is

manifested. This inner nature we know, from our previous investigation, is will, to which therefore we ascribe both the unconscious and the conscious changes of the body. The stimulus holds the mean, forms the transition between the motive, which is causality accompanied throughout by knowledge, and the cause in the narrowest sense. In particular cases it is sometimes nearer a motive, sometimes nearer a cause, but yet it can always be distinguished from both. Thus, for example, the rising of the sap in a plant follows upon stimuli, and cannot be explained from mere causes, according to the laws of hydraulics or capillary attraction; yet it is certainly assisted by these, and altogether approaches very near to a purely causal change. On the other hand, the movements of the *Hedysarum gyrans* and the *Mimosa pudica*, although still following upon mere stimuli, are yet very like movements which follow upon motives, and seem almost to wish to make the transition. The contraction of the pupils of the eyes as the light is increased is due to stimuli, but it passes into movement which is due to motive; for it takes place, because too strong lights would affect the retina painfully, and to avoid this we contract the pupils. The occasion of an erection is a motive, because it is an idea, yet it operates with the necessity of a stimulus, *i.e.*, it cannot be resisted, but we must put the idea away in order to make it cease to affect us. This is also the case with disgusting things, which excite the desire to vomit. Thus we have treated the instinct of animals as an actual link, of quite a distinct kind, between movement following upon stimuli, and action following upon a known motive. Now we might be asked to regard breathing as another link of this kind. It has been disputed whether it belongs to the voluntary or the involuntary movements, that is to say, whether it follows upon motive or stimulus, and perhaps it may be explained as something which is between the two. Marshall Hall ("On the Diseases of the Nervous System," § 293 sq.) explains it as a mixed function, for it is partly under the influence of the cerebral (voluntary), and partly under that of the spinal (non-voluntary) nerves. However, we are finally obliged to number it with the expressions of will which result from motives. For other motives, *i.e.*, mere ideas, can determine the will to check it or accelerate it, and, as is the case with every other voluntary action, it seems to us that we could give up breathing altogether and voluntarily suffocate. And in fact we could do so if any other motive influenced the will sufficiently strongly to overcome the pressing desire for air. According to some accounts Diogenes actually put an end to

his life in this way (Diog. Laert. VI. 76). Certain negroes also are said to have done this (F. B. Osiander "On Suicide" [1813] pp. 170-180). If this be true, it affords us a good example of the influence of abstract motives, *i.e.*, of the victory of distinctively rational over merely animal will. For, that breathing is at least partially conditioned by cerebral activity is shown by the fact that the primary cause of death from prussic acid is that it paralyses the brain, and so, indirectly, restricts the breathing; but if the breathing be artificially maintained till the stupefaction of the brain has passed away, death will not ensue. We may also observe in passing that breathing affords us the most obvious example of the fact that motives act with just as much necessity as stimuli, or as causes in the narrowest sense of the word, and their operation can only be neutralised by antagonistic motives, as action is neutralised by re-action. For, in the case of breathing, the illusion that we can stop when we like is much weaker than in the case of other movements which follow upon motives; because in breathing the motive is very powerful, very near to us, and its satisfaction is very easy, for the muscles which accomplish it are never tired, nothing, as a rule, obstructs it, and the whole process is supported by the most inveterate habit of the individual. And yet all motives act with the same necessity. The knowledge that necessity is common to movements following upon motives, and those following upon stimuli, makes it easier for us to understand that that also which takes place in our bodily organism in accordance with stimuli and in obedience to law, is yet, according to its inner nature — will, which in all its manifestations, though never in itself, is subordinated to the principle of sufficient reason, that is, to necessity.[32] Accordingly, we shall not rest contented with recognising that animals, both in their actions and also in their whole existence, bodily structure and organisation, are manifestations of will; but we shall extend to plants also this immediate knowledge of the essential nature of things which is given to us alone. Now all the movements of plants follow upon stimuli; for the absence of knowledge, and the movement following upon motives which is conditioned by knowledge, constitutes the only essential difference between animals and plants. Therefore, what appears for the idea as plant life, as mere vegetation, as blindly impelling force, we shall claim, according to its inner nature, for will, and recognise it as just that which constitutes the basis of our own phenomenal being, as it expresses itself in our actions, and also in the whole existence of our body itself.

It only remains for us to take the final step, the extension of our way of looking at things to all those forces which act in nature in accordance with universal, unchangeable laws, in conformity with which the movements of all those bodies take place, which are wholly without organs, and have therefore no susceptibility for stimuli, and have no knowledge, which is the necessary condition of motives. Thus we must also apply the key to the understanding of the inner nature of things, which the immediate knowledge of our own existence alone can give us, to those phenomena of the unorganised world which are most remote from us. And if we consider them attentively, if we observe the strong and unceasing impulse with which the waters hurry to the ocean, the persistency with which the magnet turns ever to the north pole, the readiness with which iron flies to the magnet, the eagerness with which the electric poles seek to be re-united, and which, just like human desire, is increased by obstacles; if we see the crystal quickly and suddenly take form with such wonderful regularity of construction, which is clearly only a perfectly definite and accurately determined impulse in different directions, seized and retained by crystallisation; if we observe the choice with which bodies repel and attract each other, combine and separate, when they are set free in a fluid state, and emancipated from the bonds of rigidness; lastly, if we feel directly how a burden which hampers our body by its gravitation towards the earth, unceasingly presses and strains upon it in pursuit of its one tendency; if we observe all this, I say, it will require no great effort of the imagination to recognise, even at so great a distance, our own nature. That which in us pursues its ends by the light of knowledge; but here, in the weakest of its manifestations, only strives blindly and dumbly in a one-sided and unchangeable manner, must yet in both cases come under the name of will, as it is everywhere one and the same — just as the first dim light of dawn must share the name of sunlight with the rays of the full mid-day. For the name *will* denotes that which is the inner nature of everything in the world, and the one kernel of every phenomenon.

Yet the remoteness, and indeed the appearance of absolute difference between the phenomena of unorganised nature and the will which we know as the inner reality of our own being, arises chiefly from the contrast between the completely determined conformity to law of the one species of phenomena, and the apparently unfettered freedom of the other. For in man, individuality makes itself powerfully felt. Every one has a character of his

own; and therefore the same motive has not the same influence over all, and a thousand circumstances which exist in the wide sphere of the knowledge of the individual, but are unknown to others, modify its effect. Therefore action cannot be predetermined from the motive alone, for the other factor is wanting, the accurate acquaintance with the individual character, and with the knowledge which accompanies it. On the other hand, the phenomena of the forces of nature illustrate the opposite extreme. They act according to universal laws, without variation, without individuality in accordance with openly manifest circumstances, subject to the most exact predetermination; and the same force of nature appears in its million phenomena in precisely the same way. In order to explain this point and prove the identity of the *one* indivisible will in all its different phenomena, in the weakest as in the strongest, we must first of all consider the relation of the will as thing-in-itself to its phenomena, that is, the relation of the world as will to the world as idea; for this will open to us the best way to a more thorough investigation of the whole subject we are considering in this second book.[33]

§ 24. We have learnt from the great Kant that time, space, and causality, with their entire constitution, and the possibility of all their forms, are present in our consciousness quite independently of the objects which appear in them, and which constitute their content; or, in other words, they can be arrived at just as well if we start from the subject as if we start from the object. Therefore, with equal accuracy, we may call them either forms of intuition or perception of the subject, or qualities of the object *as object* (with Kant, phenomenon), *i.e.*, *idea*. We may also regard these forms as the irreducible boundary between object and subject. All objects must therefore exist in them, yet the subject, independently of the phenomenal object, possesses and surveys them completely. But if the objects appearing in these forms are not to be empty phantoms, but are to have a meaning, they must refer to something, must be the expression of something which is not, like themselves, object, idea, a merely relative existence for a subject, but which exists without such dependence upon something which stands over against it as a condition of its being, and independent of the forms of such a thing, *i.e.*, *is not idea*, but a *thing-in-itself*. Consequently it may at least be asked: Are these ideas, these objects, something more than or apart from the fact that they are ideas, objects of the subject? And what would they be in this sense? What is that other side of them which is *toto genere* different

from idea? What is the thing-in-itself? *The will*, we have answered, but for the present I set that answer aside.

Whatever the thing-in-itself may be, Kant is right in his conclusion that time, space, and causality (which we afterwards found to be forms of the principle of sufficient reason, the general expression of the forms of the phenomenon) are not its properties, but come to it only after, and so far as, it has become idea. That is, they belong only to its phenomenal existence, not to itself. For since the subject fully understands and constructs them out of itself, independently of all object, they must be dependent upon *existence as idea* as such, not upon that which becomes idea. They must be the form of the idea as such; but not qualities of that which has assumed this form. They must be already given with the mere antithesis of subject and object (not as concepts but as facts), and consequently they must be only the more exact determination of the form of knowledge in general, whose most universal determination is that antithesis itself. Now, that in the phenomenon, in the object, which is in its turn conditioned by time, space and causality, inasmuch as it can only become idea by means of them, namely *multiplicity*, through co-existence and succession, *change* and *permanence* through the law of causality, *matter* which can only become idea under the presupposition of causality, and lastly, all that becomes idea only by means of these, — all this, I say, as a whole, does not in reality belong to that which appears, to that which has passed into the form of idea, but belongs merely to this form itself. And conversely, that in the phenomenon which is not conditioned through time, space and causality, and which cannot be referred to them, nor explained in accordance with them, is precisely that in which the thing manifested, the thing-in-itself, directly reveals itself. It follows from this that the most complete capacity for being known, that is to say, the greatest clearness, distinctness, and susceptibility of exhaustive explanation, will necessarily belong to that which pertains to knowledge *as such*, and thus to the *form* of knowledge; but not to that which in itself is not idea, not object, but which has become knowledge only through entering these forms; in other words, has become idea, object. Thus only that which depends entirely upon being an object of knowledge, upon existing as idea in general and *as such* (not upon that which *becomes* known, and has only *become* idea), which therefore belongs without distinction to everything that is known, and which, on that account, is found just as well if we start from the subject as if we start from the

object, — this alone can afford us without reserve a sufficient, exhaustive knowledge, a knowledge which is clear to the very foundation. But this consists of nothing but those forms of all phenomena of which we are conscious *a priori*, and which may be generally expressed as the principle of sufficient reason. Now, the forms of this principle which occur in knowledge of perception (with which alone we are here concerned) are time, space, and causality. The whole of pure mathematics and pure natural science *a priori* is based entirely upon these. Therefore it is only in these sciences that knowledge finds no obscurity, does not rest upon what is incomprehensible (groundless, *i.e.*, will), upon what cannot be further deduced. It is on this account that Kant wanted, as we have said, to apply the name science specially and even exclusively to these branches of knowledge together with logic. But, on the other hand, these branches of knowledge show us nothing more than mere connections, relations of one idea to another, form devoid of all content. All content which they receive, every phenomenon which fills these forms, contains something which is no longer completely knowable in its whole nature, something which can no longer be entirely explained through something else, something then which is groundless, through which consequently the knowledge loses its evidence and ceases to be completely lucid. This that withholds itself from investigation, however, is the thing-in-itself, is that which is essentially not idea, not object of knowledge, but has only become knowable by entering that form. The form is originally foreign to it, and the thing-in-itself can never become entirely one with it, can never be referred to mere form, and, since this form is the principle of sufficient reason, can never be completely explained. If therefore all mathematics affords us an exhaustive knowledge of that which in the phenomena is quantity, position, number, in a word, spatial and temporal relations; if all etiology gives us a complete account of the regular conditions under which phenomena, with all their determinations, appear in time and space, but, with it all, teaches us nothing more than why in each case this particular phenomenon must appear just at this time here, and at this place now; it is clear that with their assistance we can never penetrate to the inner nature of things. There always remains something which no explanation can venture to attack, but which it always presupposes; the forces of nature, the definite mode of operation of things, the quality and character of every phenomenon, that which is without ground, that which does not depend upon the form of the phenomenal, the

principle of sufficient reason, but is something to which this form in itself is foreign, something which has yet entered this form, and now appears according to its law, a law, however, which only determines the appearance, not that which appears, only the how, not the what, only the form, not the content. Mechanics, physics, and chemistry teach the rules and laws according to which the forces of impenetrability, gravitation, rigidity, fluidity, cohesion, elasticity, heat, light, affinity, magnetism, electricity, &c., operate; that is to say, the law, the rule which these forces observe whenever they enter time and space. But do what we will, the forces themselves remain *qualitates occultæ*. For it is just the thing-in-itself, which, because it is manifested, exhibits these phenomena, which are entirely different from itself. In its manifestation, indeed, it is completely subordinated to the principle of sufficient reason as the form of the idea, but it can never itself be referred to this form, and therefore cannot be fully explained etiologically, can never be completely fathomed. It is certainly perfectly comprehensible so far as it has assumed that form, that is, so far as it is phenomenon, but its inner nature is not in the least explained by the fact that it can thus be comprehended. Therefore the more necessity any knowledge carries with it, the more there is in it of that which cannot be otherwise thought or presented in perception — as, for example, space-relations — the clearer and more sufficing then it is, the less pure objective content it has, or the less reality, properly so called, is given in it. And conversely, the more there is in it which must be conceived as mere chance, and the more it impresses us as given merely empirically, the more proper objectivity and true reality is there in such knowledge, and at the same time, the more that is inexplicable, that is, that cannot be deduced from anything else.

It is true that at all times an etiology, unmindful of its real aim, has striven to reduce all organised life to chemism or electricity; all chemism, that is to say quality, again to mechanism (action determined by the shape of the atom), this again sometimes to the object of phoronomy, *i.e.*, the combination of time and space, which makes motion possible, sometimes to the object of mere geometry, *i.e.*, position in space (much in the same way as we rightly deduce the diminution of an effect from the square of the distance, and the theory of the lever in a purely geometrical manner): geometry may finally be reduced to arithmetic, which, on account of its one dimension, is of all the forms of the principle of sufficient reason, the most

intelligible, comprehensible, and completely susceptible of investigation. As instances of the method generally indicated here, we may refer to the atoms of Democritus, the vortex of Descartes, the mechanical physics of Lesage, which towards the end of last century tried to explain both chemical affinities and gravitation mechanically by impact and pressure, as may be seen in detail in "*Lucrèce Neutonien*;" Reil's form and combination as the cause of animal life, also tends in this direction. Finally, the crude materialism which even now in the middle of the nineteenth century has been served up again under the ignorant delusion that it is original, belongs distinctly to this class. It stupidly denies vital force, and first of all tries to explain the phenomena of life from physical and chemical forces, and those again from the mechanical effects of the matter, position, form, and motion of imagined atoms, and thus seeks to reduce all the forces of nature to action and reaction as its thing-in-itself. According to this teaching, light is the mechanical vibration or undulation of an imaginary ether, postulated for this end. This ether, if it reaches the eye, beats rapidly upon the retina, and gives us the knowledge of colour. Thus, for example, four hundred and eighty-three billion beats in a second give red, and seven hundred and twenty-seven billion beats in a second give violet. Upon this theory, persons who are colour-blind must be those who are unable to count the beats, must they not? Such crass, mechanical, clumsy, and certainly knotty theories, which remind one of Democritus, are quite worthy of those who, fifty years after the appearance of Goethe's doctrine of colour, still believe in Newton's homogeneous light, and are not ashamed to say so. They will find that what is overlooked in the child (Democritus) will not be forgiven to the man. They might indeed, some day, come to an ignominious end; but then every one would slink away and pretend that he never had anything to do with them. We shall soon have to speak again of this false reduction of the forces of nature to each other; so much for the present. Supposing this theory were possible, all would certainly be explained and established and finally reduced to an arithmetical problem, which would then be the holiest thing in the temple of wisdom, to which the principle of sufficient reason would at last have happily conducted us. But all content of the phenomenon would have disappeared, and the mere form would remain. The "what appears" would be referred to the "how it appears," and this "how" would be what is *a priori* knowable, therefore entirely dependent on the subject, therefore only for the subject, therefore, lastly, mere phantom, idea and form of idea,

through and through: no thing-in-itself could be demanded. Supposing, then, that this were possible, the whole world would be derived from the subject, and in fact, that would be accomplished which Fichte wanted to *seem* to accomplish by his empty bombast. But it is not possible: phantasies, sophisms, castles in the air, have been constructed in this way, but science never. The many and multifarious phenomena in nature have been successfully referred to particular original forces, and as often as this has been done, a real advance has been made. Several forces and qualities, which were at first regarded as different, have been derived from each other, and thus their number has been curtailed. (For example, magnetism from electricity.) Etiology will have reached its goal when it has recognised and exhibited as such all the original forces of nature, and established their mode of operation, *i.e.*, the law according to which, under the guidance of causality, their phenomena appear in time and space, and determine their position with regard to each other. But certain original forces will always remain over; there will always remain as an insoluble residuum a content of phenomena which cannot be referred to their form, and thus cannot be explained from something else in accordance with the principle of sufficient reason. For in everything in nature there is something of which no ground can ever be assigned, of which no explanation is possible, and no ulterior cause is to be sought. This is the specific nature of its action, *i.e.*, the nature of its existence, its being. Of each particular effect of the thing a cause may be certainly indicated, from which it follows that it must act just at this time and in this place; but no cause can ever be found from which it follows that a thing acts in general, and precisely in the way it does. If it has no other qualities, if it is merely a mote in a sunbeam, it yet exhibits this unfathomable something, at least as weight and impenetrability. But this, I say, is to the mote what his will is to a man; and, like the human will, it is, according to its inner nature, not subject to explanation; nay, more — it is in itself identical with this will. It is true that a motive may be given for every manifestation of will, for every act of will at a particular time and in a particular place, upon which it must necessarily follow, under the presupposition of the character of the man. But no reason can ever be given that the man has this character; that he wills at all; that, of several motives, just this one and no other, or indeed that any motive at all, moves his will. That which in the case of man is the unfathomable character which is presupposed in every explanation of his actions from motives is, in the case

of every unorganised body, its definitive quality — the mode of its action, the manifestations of which are occasioned by impressions from without, while it itself, on the contrary, is determined by nothing outside itself, and thus is also inexplicable. Its particular manifestations, through which alone it becomes visible, are subordinated to the principle of sufficient reason; it itself is groundless. This was in substance rightly understood by the schoolmen, who called it *forma substantialis*. (Cf. Suarez, Disput. Metaph., disp. xv. sect. 1.)

It is a greater and a commoner error that the phenomena which we best understand are those which are of most frequent occurrence, and which are most universal and simple; for, on the contrary, these are just the phenomena that we are most accustomed to see about us, and to be ignorant of. It is just as inexplicable to us that a stone should fall to the earth as that an animal should move itself. It has been supposed, as we have remarked above, that, starting from the most universal forces of nature (gravitation, cohesion, impenetrability), it was possible to explain from them the rarer forces, which only operate under a combination of circumstances (for example, chemical quality, electricity, magnetism), and, lastly, from these to understand the organism and the life of animals, and even the nature of human knowing and willing. Men resigned themselves without a word to starting from mere *qualitates occultæ*, the elucidation of which was entirely given up, for they intended to build upon them, not to investigate them. Such an intention cannot, as we have already said, be carried out. But apart from this, such structures would always stand in the air. What is the use of explanations which ultimately refer us to something which is quite as unknown as the problem with which we started? Do we in the end understand more of the inner nature of these universal natural forces than of the inner nature of an animal? Is not the one as much a sealed book to us as the other? Unfathomable because it is without ground, because it is the content, that which the phenomenon is, and which can never be referred to the form, to the how, to the principle of sufficient reason. But we, who have in view not etiology but philosophy, that is, not relative but unconditioned knowledge of the real nature of the world, take the opposite course, and start from that which is immediately and most completely known to us, and fully and entirely trusted by us — that which lies nearest to us, in order to understand that which is known to us only at a distance, one-sidedly and indirectly. From the most powerful, most significant, and most distinct

phenomenon we seek to arrive at an understanding of those that are less complete and weaker. With the exception of my own body, all things are known to me only on *one* side, that of the idea. Their inner nature remains hidden from me and a profound secret, even if I know all the causes from which their changes follow. Only by comparison with that which goes on in me if my body performs an action when I am influenced by a motive — only by comparison, I say, with what is the inner nature of my own changes determined by external reasons, can I obtain insight into the way in which these lifeless bodies change under the influence of causes, and so understand what is their inner nature. For the knowledge of the causes of the manifestation of this inner nature affords me merely the rule of its appearance in time and space, and nothing more. I can make this comparison because my body is the only object of which I know not merely the *one* side, that of the idea, but also the other side which is called will. Thus, instead of believing that I would better understand my own organisation, and then my own knowing and willing, and my movements following upon motives, if I could only refer them to movements due to electrical, chemical, and mechanical causes, I must, seeing that I seek philosophy and not etiology, learn to understand from my own movements following upon motives the inner nature of the simplest and commonest movements of an unorganised body which I see following upon causes. I must recognise the inscrutable forces which manifest themselves in all natural bodies as identical in kind with that which in me is the will, and as differing from it only in degree. That is to say, the fourth class of ideas given in the Essay on the Principle of Sufficient Reason must be the key to the knowledge of the inner nature of the first class, and by means of the law of motivation I must come to understand the inner meaning of the law of causation.

Spinoza (Epist. 62) says that if a stone which has been projected through the air had consciousness, it would believe that it was moving of its own will. I add to this only that the stone would be right. The impulse given it is for the stone what the motive is for me, and what in the case of the stone appears as cohesion, gravitation, rigidity, is in its inner nature the same as that which I recognise in myself as will, and what the stone also, if knowledge were given to it, would recognise as will. In the passage referred to, Spinoza had in view the necessity with which the stone flies, and he rightly desires to transfer this necessity to that of the particular act of will of

a person. I, on the other hand, consider the inner being, which alone imparts meaning and validity to all real necessity (*i.e.*, effect following upon a cause) as its presupposition. In the case of men this is called character; in the case of a stone it is called quality, but it is the same in both. When it is immediately known it is called will. In the stone it has the weakest, and in man the strongest degree of visibility, of objectivity. St. Augustine recognises, with a true instinct, this identity of the tendencies of all things with our own willing, and I cannot refrain from quoting his naïve account of the matter:— "*Si pecora essemus, carnalem vitam et quod secundum sensum ejusdem est amaremus, idque esset sufficiens bonum nostrum, et secundum hoc si esset nobis bene, nihil aliud quæreremus. Item, si arbores essemus, nihil quidem sentientes motu amare possemus: verumtamen id quasi appetere videremur, quo feracius essemus, uberiusque fructuosæ. Si essemus lapides, aut fluctus, aut ventus, aut flamma, vel quid ejusmodi, sine ullo quidem sensu atque vita, non tamen nobis deesset quasi quidam nostrorum locorum atque ordinis appetitus. Nam velut amores corporum momenta sunt ponderum, sive deorsum gravitate, sive sursum levitate nitantur: ita enim corpus pondere, sicut animus amore fertur quocunque fertur*" (De Civ. Dei, xi. 28).

It ought further to be mentioned that Euler saw that the inner nature of gravitation must ultimately be referred to an "inclination and desire" (thus will) peculiar to material bodies (in the 68th letter to the Princess). Indeed, it is just this that makes him averse to the conception of gravitation as it existed for Newton, and he is inclined to try a modification of it in accordance with the earlier Cartesian theory, and so to derive gravitation from the impact of an ether upon the bodies, as being "more rational and more suitable for persons who like clear and intelligible principles." He wishes to banish attraction from physics as a *qualitas occulta*. This is only in keeping with the dead view of nature which prevailed at Euler's time as the correlative of the immaterial soul. It is only worth noticing because of its bearing upon the fundamental truth established by me, which even at that time this fine intellect saw glimmering in the distance. He hastened to turn in time, and then, in his anxiety at seeing all the prevalent fundamental views endangered, he sought safety in the old and already exploded absurdities.

We know that *multiplicity* in general is necessarily conditioned by space and time, and is only thinkable in them. In this respect they are called the *principium individuationis*. But we have found that space and time are forms of the principle of sufficient reason. In this principle all our knowledge *a priori* is expressed, but, as we showed above, this *a priori* knowledge, as such, only applies to the knowableness of things, not to the things themselves, *i.e.*, it is only our form of knowledge, it is not a property of the thing-in-itself. The thing-in-itself is, as such, free from all forms of knowledge, even the most universal, that of being an object for the subject. In other words, the thing-in-itself is something altogether different from the idea. If, now, this thing-in-itself is *the will*, as I believe I have fully and convincingly proved it to be, then, regarded as such and apart from its manifestation, it lies outside time and space, and therefore knows no multiplicity, and is consequently *one*. Yet, as I have said, it is not one in the sense in which an individual or a concept is one, but as something to which the condition of the possibility of multiplicity, the *principium individuationis*, is foreign. The multiplicity of things in space and time, which collectively constitute the objectification of will, does not affect the will itself, which remains indivisible notwithstanding it. It is not the case that, in some way or other, a smaller part of will is in the stone and a larger part in the man, for the relation of part and whole belongs exclusively to space, and has no longer any meaning when we go beyond this form of intuition or perception. The more and the less have application only to the phenomenon of will, that is, its visibility, its objectification. Of this there is a higher grade in the plant than in the stone; in the animal a higher grade than in the plant: indeed, the passage of will into visibility, its objectification, has grades as innumerable as exist between the dimmest twilight and the brightest sunshine, the loudest sound and the faintest echo. We shall return later to the consideration of these grades of visibility which belong to the objectification of the will, to the reflection of its nature. But as the grades of its objectification do not directly concern the will itself, still less is it concerned by the multiplicity of the phenomena of these different grades, *i.e.*, the multitude of individuals of each form, or the particular manifestations of each force. For this multiplicity is directly conditioned by time and space, into which the will itself never enters. The will reveals itself as completely and as much in *one* oak as in millions. Their number and multiplication in space and time has no meaning with regard to it, but only

with regard to the multiplicity of individuals who know in space and time, and who are themselves multiplied and dispersed in these. The multiplicity of these individuals itself belongs not to the will, but only to its manifestation. We may therefore say that if, *per impossibile*, a single real existence, even the most insignificant, were to be entirely annihilated, the whole world would necessarily perish with it. The great mystic Angelus Silesius feels this when he says —

"I know God cannot live an instant without me,
He must give up the ghost if I should cease to be."

Men have tried in various ways to bring the immeasurable greatness of the material universe nearer to the comprehension of us all, and then they have seized the opportunity to make edifying remarks. They have referred perhaps to the relative smallness of the earth, and indeed of man; or, on the contrary, they have pointed out the greatness of the mind of this man who is so insignificant — the mind that can solve, comprehend, and even measure the greatness of the universe, and so forth. Now, all this is very well, but to me, when I consider the vastness of the world, the most important point is this, that the thing-in-itself, whose manifestation is the world — whatever else it may be — cannot have its true self spread out and dispersed after this fashion in boundless space, but that this endless extension belongs only to its manifestation. The thing-in-itself, on the contrary, is present entire and undivided in every object of nature and in every living being. Therefore we lose nothing by standing still beside any single individual thing, and true wisdom is not to be gained by measuring out the boundless world, or, what would be more to the purpose, by actually traversing endless space. It is rather to be attained by the thorough investigation of any individual thing, for thus we seek to arrive at a full knowledge and understanding of its true and peculiar nature.

The subject which will therefore be fully considered in the next book, and which has, doubtless, already presented itself to the mind of every student of Plato, is, that these different grades of the objectification of will which are manifested in innumerable individuals, and exist as their unattained types or as the eternal forms of things, not entering themselves into time and space, which are the medium of individual things, but remaining fixed, subject to no change, always being, never becoming, while the particular things arise and pass away, always become and never are, — that these *grades of the objectification of will* are, I say, simply *Plato's*

Ideas. I make this passing reference to the matter here in order that I may be able in future to use the word *Idea* in this sense. In my writings, therefore, the word is always to be understood in its true and original meaning given to it by Plato, and has absolutely no reference to those abstract productions of dogmatising scholastic reason, which Kant has inaptly and illegitimately used this word to denote, though Plato had already appropriated and used it most fitly. By Idea, then, I understand every definite and fixed grade of the objectification of will, so far as it is thing-in-itself, and therefore has no multiplicity. These grades are related to individual things as their eternal forms or prototypes. The shortest and most concise statement of this famous Platonic doctrine is given us by Diogenes Laertes (iii. 12): "ὁ Πλατων φησι, εν τῃ φυσει τας ιδεας ἑσταναι, καθαπερ παραδειγματα, τα δ᾽ αλλα ταυταις εοικεναι, τουτων ὁμοιωματα καθεστωτα" — ("*Plato ideas in natura velut exemplaria dixit subsistere; cetera his esse similia, ad istarum similitudinem consistentia*"). Of Kant's misuse of the word I take no further notice; what it is needful to say about it will be found in the Appendix.

§ 26. The lowest grades of the objectification of will are to be found in those most universal forces of nature which partly appear in all matter without exception, as gravity and impenetrability, and partly have shared the given matter among them, so that certain of them reign in one species of matter and others in another species, constituting its specific difference, as rigidity, fluidity, elasticity, electricity, magnetism, chemical properties and qualities of every kind. They are in themselves immediate manifestations of will, just as much as human action; and as such they are groundless, like human character. Only their particular manifestations are subordinated to the principle of sufficient reason, like the particular actions of men. They themselves, on the other hand, can never be called either effect or cause, but are the prior and presupposed conditions of all causes and effects through which their real nature unfolds and reveals itself. It is therefore senseless to demand a cause of gravity or electricity, for they are original forces. Their expressions, indeed, take place in accordance with the law of cause and effect, so that every one of their particular manifestations has a cause, which is itself again just a similar particular manifestation which determines that this force must express itself here, must appear in space and time; but the force itself is by no means the effect of a cause, nor the cause of an effect. It is therefore a mistake to say "gravity is the cause of a stone falling;" for the cause in this case is rather the nearness of the earth, because

it attracts the stone. Take the earth away and the stone will not fall, although gravity remains. The force itself lies quite outside the chain of causes and effects, which presupposes time, because it only has meaning in relation to it; but the force lies outside time. The individual change always has for its cause another change just as individual as itself, and not the force of which it is the expression. For that which always gives its efficiency to a cause, however many times it may appear, is a force of nature. As such, it is groundless, *i.e.*, it lies outside the chain of causes and outside the province of the principle of sufficient reason in general, and is philosophically known as the immediate objectivity of will, which is the "in-itself" of the whole of nature; but in etiology, which in this reference is physics, it is set down as an original force, *i.e.*, a *qualitas occulta*.

In the higher grades of the objectivity of will we see individuality occupy a prominent position, especially in the case of man, where it appears as the great difference of individual characters, *i.e.*, as complete personality, outwardly expressed in strongly marked individual physiognomy, which influences the whole bodily form. None of the brutes have this individuality in anything like so high a degree, though the higher species of them have a trace of it; but the character of the species completely predominates over it, and therefore they have little individual physiognomy. The farther down we go, the more completely is every trace of the individual character lost in the common character of the species, and the physiognomy of the species alone remains. We know the physiological character of the species, and from that we know exactly what is to be expected from the individual; while, on the contrary, in the human species every individual has to be studied and fathomed for himself, which, if we wish to forecast his action with some degree of certainty, is, on account of the possibility of concealment that first appears with reason, a matter of the greatest difficulty. It is probably connected with this difference of the human species from all others, that the folds and convolutions of the brain, which are entirely wanting in birds, and very weakly marked in rodents, are even in the case of the higher animals far more symmetrical on both sides, and more constantly the same in each individual, than in the case of human beings.[34] It is further to be regarded as a phenomenon of this peculiar individual character which distinguishes men from all the lower animals, that in the case of the brutes the sexual instinct seeks its satisfaction without observable choice of objects, while in the case of man this choice is, in a purely instinctive manner and independent of all

reflection, carried so far that it rises into a powerful passion. While then every man is to be regarded as a specially determined and characterised phenomenon of will, and indeed to a certain extent as a special Idea, in the case of the brutes this individual character as a whole is wanting, because only the species has a special significance. And the farther we go from man, the fainter becomes the trace of this individual character, so that plants have no individual qualities left, except such as may be fully explained from the favourable or unfavourable external influences of soil, climate, and other accidents. Finally, in the inorganic kingdom of nature all individuality disappears. The crystal alone is to be regarded as to a certain extent individual. It is a unity of the tendency in definite directions, fixed by crystallisation, which makes the trace of this tendency permanent. It is at the same time a cumulative repetition of its primitive form, bound into unity by an idea, just as the tree is an aggregate of the single germinating fibre which shows itself in every rib of the leaves, in every leaf, in every branch; which repeats itself, and to some extent makes each of these appear as a separate growth, nourishing itself from the greater as a parasite, so that the tree, resembling the crystal, is a systematic aggregate of small plants, although only the whole is the complete expression of an individual Idea, *i.e.*, of this particular grade of the objectification of will. But the individuals of the same species of crystal can have no other difference than such as is produced by external accidents; indeed we can make at pleasure large or small crystals of every species. The individual, however, as such, that is, with traces of an individual character, does not exist further in unorganised nature. All its phenomena are expressions of general forces of nature, *i.e.*, of those grades of the objectification of will which do not objectify themselves (as is the case in organised nature), by means of the difference of the individualities which collectively express the whole of the Idea, but show themselves only in the species, and as a whole, without any variation in each particular example of it. Time, space, multiplicity, and existence conditioned by causes, do not belong to the will or to the Idea (the grade of the objectification of will), but only to their particular phenomena. Therefore such a force of nature as, for example, gravity or electricity, must show itself as such in precisely the same way in all its million phenomena, and only external circumstances can modify these. This unity of its being in all its phenomena, this unchangeable constancy of the appearance of these, whenever, under the guidance of causality, the necessary conditions are

present, is called a *law of nature*. If such a law is once learned from experience, then the phenomenon of that force of nature, the character of which is expressed and laid down in it, may be accurately forecast and counted upon. But it is just this conformity to law of the phenomena of the lower grades of the objectification of will which gives them such a different aspect from the phenomena of the same will in the higher, *i.e.*, the more distinct, grades of its objectification, in animals, and in men and their actions, where the stronger or weaker influence of the individual character and the susceptibility to motives which often remain hidden from the spectator, because they lie in knowledge, has had the result that the identity of the inner nature of the two kinds of phenomena has hitherto been entirely overlooked.

If we start from the knowledge of the particular, and not from that of the Idea, there is something astonishing, and sometimes even terrible, in the absolute uniformity of the laws of nature. It might astonish us that nature never once forgets her laws; that if, for example, it has once been according to a law of nature that where certain materials are brought together under given conditions, a chemical combination will take place, or gas will be evolved, or they will go on fire; if these conditions are fulfilled, whether by our interposition or entirely by chance (and in this case the accuracy is the more astonishing because unexpected), to-day just as well as a thousand years ago, the determined phenomenon will take place at once and without delay. We are most vividly impressed with the marvellousness of this fact in the case of rare phenomena, which only occur under very complex circumstances, but which we are previously informed will take place if these conditions are fulfilled. For example, when we are told that if certain metals, when arranged alternately in fluid with which an acid has been mixed, are brought into contact, silver leaf brought between the extremities of this combination will suddenly be consumed in a green flame; or that under certain conditions the hard diamond turns into carbonic acid. It is the ghostly omnipresence of natural forces that astonishes us in such cases, and we remark here what in the case of phenomena which happen daily no longer strikes us, how the connection between cause and effect is really as mysterious as that which is imagined between a magic formula and a spirit that must appear when invoked by it. On the other hand, if we have attained to the philosophical knowledge that a force of nature is a definite grade of the objectification of will, that is to say, a definite grade of that which we

recognise as our own inmost nature, and that this will, in itself, and distinguished from its phenomena and their forms, lies outside time and space, and that, therefore, the multiplicity, which is conditioned by time and space, does not belong to it, nor directly to the grade of its objectification, *i.e.*, the Idea, but only to the phenomena of the Idea; and if we remember that the law of causality has significance only in relation to time and space, inasmuch as it determines the position of the multitude of phenomena of the different Ideas in which the will reveals itself, governing the order in which they must appear; if, I say, in this knowledge the inner meaning of the great doctrine of Kant has been fully grasped, the doctrine that time, space, and causality do not belong to the thing-in-itself, but merely to the phenomenon, that they are only the forms of our knowledge, not qualities of things in themselves; then we shall understand that this astonishment at the conformity to law and accurate operation of a force of nature, this astonishment at the complete sameness of all its million phenomena and the infallibility of their occurrence, is really like that of a child or a savage who looks for the first time through a glass with many facets at a flower, and marvels at the complete similarity of the innumerable flowers which he sees, and counts the leaves of each of them separately.

Thus every universal, original force of nature is nothing but a low grade of the objectification of will, and we call every such grade an eternal *Idea* in Plato's sense. But a *law of nature* is the relation of the Idea to the form of its manifestation. This form is time, space, and causality, which are necessarily and inseparably connected and related to each other. Through time and space the Idea multiplies itself in innumerable phenomena, but the order according to which it enters these forms of multiplicity is definitely determined by the law of causality; this law is as it were the norm of the limit of these phenomena of different Ideas, in accordance with which time, space, and matter are assigned to them. This norm is therefore necessarily related to the identity of the aggregate of existing matter, which is the common substratum of all those different phenomena. If all these were not directed to that common matter in the possession of which they must be divided, there would be no need for such a law to decide their claims. They might all at once and together fill a boundless space throughout an endless time. Therefore, because all these phenomena of the eternal Ideas are directed to one and the same matter, must there be a rule for their appearance and disappearance; for if there were not, they would not make

way for each other. Thus the law of causality is essentially bound up with that of the permanence of substance; they reciprocally derive significance from each other. Time and space, again, are related to them in the same way. For time is merely the possibility of conflicting states of the same matter, and space is merely the possibility of the permanence of the same matter under all sorts of conflicting states. Accordingly, in the preceding book we explained matter as the union of space and time, and this union shows itself as change of the accidents in the permanence of the substance, of which causality or becoming is the universal possibility. And accordingly, we said that matter is through and through causality. We explained the understanding as the subjective correlative of causality, and said matter (and thus the whole world as idea) exists only for the understanding; the understanding is its condition, its supporter as its necessary correlative. I repeat all this in passing, merely to call to mind what was demonstrated in the First Book, for it is necessary for the complete understanding of these two books that their inner agreement should be observed, since what is inseparably united in the actual world as its two sides, will and idea, has, in order that we might understand each of them more clearly in isolation, been dissevered in these two books.

It may not perhaps be superfluous to elucidate further by an example how the law of causality has meaning only in relation to time and space, and the matter which consists in the union of the two. For it determines the limits in accordance with which the phenomena of the forces of nature divide themselves in the possession of matter, while the original forces of nature, as the immediate objectification of will, which, as a thing in itself, is not subordinated to the principle of sufficient reason, lie outside these forms, within which alone all etiological explanation has validity and meaning, and just on that account can never lead us to the inner reality of nature. For this purpose let us think of some kind of machine constructed according to the laws of mechanics. Iron weights begin the motion by their gravity; copper wheels resist by their rigidity, affect and raise each other and the lever by their impenetrability, and so on. Here gravity, rigidity, and impenetrability are original unexplained forces; mechanics only gives us the condition under which, and the manner in which, they manifest themselves, appear, and govern a definite matter, time, and place. If, now, a strong magnet is made to attract the iron of the weight, and overcome its gravity, the movement of the machine stops, and the matter becomes forthwith the

scene of quite a different force of nature — magnetism, of which etiology again gives no further explanation than the condition under which it appears. Or let us suppose that the copper discs of such a machine are laid upon zinc plates, and an acid solution introduced between them. At once the same matter of the machine has become subject to another original force, galvanism, which now governs it according to its own laws, and reveals itself in it through its phenomena; and etiology can again tell us nothing about this force except the conditions under which, and the laws in accordance with which, it manifests itself. Let us now raise the temperature and add pure acid; the whole machine burns; that is to say, once more an entirely different force of nature, chemical energy, asserts at this time and in this place irresistible claims to this particular matter, and reveals itself in it as Idea, as a definite grade of the objectification of will. The calcined metal thus produced now unites with an acid, and a salt is obtained which forms itself into crystals. These are the phenomena of another Idea, which in itself is again quite inexplicable, while the appearance of its phenomena is dependent upon certain conditions which etiology can give us. The crystals dissolve, mix with other materials, and vegetation springs up from them — a new phenomenon of will: and so the same permanent matter may be followed *ad infinitum*, to observe how now this and now that natural force obtains a right to it and temporarily takes possession of it, in order to appear and reveal its own nature. The condition of this right, the point of time and space at which it becomes valid, is given by causality, but the explanation founded upon this law only extends thus far. The force itself is a manifestation of will, and as such is not subject to the forms of the principle of sufficient reason, that is, it is groundless. It lies outside all time, is omnipresent, and seems as it were to wait constantly till the circumstances occur under which it can appear and take possession of a definite matter, supplanting the forces which have reigned in it till then. All time exists only for the phenomena of such a force, and is without significance for the force itself. Through thousands of years chemical forces slumber in matter till the contact with the reagents sets them free; then they appear; but time exists only for the phenomena, not for the forces themselves. For thousands of years galvanism slumbered in copper and zinc, and they lay quietly beside silver, which must be consumed in flame as soon as all three are brought together under the required conditions. Even in the organic kingdom we see

a dry seed preserve the slumbering force through three thousand years, and when at last the favourable circumstances occur, grow up as a plant.[35]

If by this exposition the difference between a force of nature and all its phenomena has been made quite distinct; if we have seen clearly that the former is the will itself at this particular grade of its objectification, but that multiplicity comes to phenomena only through time and space, and that the law of causality is nothing but the determination of the position of these phenomena in time and space; then we shall recognise the complete truth and the deep meaning of Malebranche's doctrine of occasional causes (*causes occasionelles*). It is well worth while comparing this doctrine of his, as he explains it in the "*Recherches de la Vérite*," both in the 3rd Chapter of the second part of the 6th Book, and in the *éclaircissements* appended to this chapter, with this exposition of mine, and observing the complete agreement of the two doctrines in the case of such different systems of thought. Indeed I cannot help admiring how Malebranche, though thoroughly involved in the positive dogmas which his age inevitably forced upon him, yet, in such bonds and under such a burden, hit the truth so happily, so correctly, and even knew how to combine it with these dogmas, at all events verbally.

For the power of truth is incredibly great and of unspeakable endurance. We find constant traces of it in all, even the most eccentric and absurd dogmas, of different times and different lands, — often indeed in strange company, curiously mixed up with other things, but still recognisable. It is like a plant that germinates under a heap of great stones, but still struggles up to the light, working itself through with many deviations and windings, disfigured, worn out, stunted in its growth, — but yet, to the light.

In any case Malebranche is right: every natural cause is only an occasional cause. It only gives opportunity or occasion for the manifestation of the one indivisible will which is the "in-itself" of all things, and whose graduated objectification is the whole visible world. Only the appearance, the becoming visible, in this place, at this time, is brought about by the cause and is so far dependent on it, but not the whole of the phenomenon, nor its inner nature. This is the will itself, to which the principle of sufficient reason has not application, and which is therefore groundless. Nothing in the world has a sufficient cause of its existence generally, but only a cause of existence just here and just now. That a stone exhibits now gravity, now rigidity, now electricity, now chemical qualities, depends upon

causes, upon impressions upon it from without, and is to be explained from these. But these qualities themselves, and thus the whole inner nature of the stone which consists in them, and therefore manifests itself in all the ways referred to; thus, in general, that the stone is such as it is, that it exists generally — all this, I say, has no ground, but is the visible appearance of the groundless will. Every cause is thus an occasional cause. We have found it to be so in nature, which is without knowledge, and it is also precisely the same when motives and not causes or stimuli determine the point at which the phenomena are to appear, that is to say, in the actions of animals and human beings. For in both cases it is one and the same will which appears; very different in the grades of its manifestation, multiplied in the phenomena of these grades, and, in respect of these, subordinated to the principle of sufficient reason, but in itself free from all this. Motives do not determine the character of man, but only the phenomena of his character, that is, his actions; the outward fashion of his life, not its inner meaning and content. These proceed from the character which is the immediate manifestation of the will, and is therefore groundless. That one man is bad and another good, does not depend upon motives or outward influences, such as teaching and preaching, and is in this sense quite inexplicable. But whether a bad man shows his badness in petty acts of injustice, cowardly tricks, and low knavery which he practises in the narrow sphere of his circumstances, or whether as a conqueror he oppresses nations, throws a world into lamentation, and sheds the blood of millions; this is the outward form of his manifestation, that which is unessential to it, and depends upon the circumstances in which fate has placed him, upon his surroundings, upon external influences, upon motives; but his decision upon these motives can never be explained from them; it proceeds from the will, of which this man is a manifestation. Of this we shall speak in the Fourth Book. The manner in which the character discloses its qualities is quite analogous to the way in which those of every material body in unconscious nature are disclosed. Water remains water with its intrinsic qualities, whether as a still lake it reflects its banks, or leaps in foam from the cliffs, or, artificially confined, spouts in a long jet into the air. All that depends upon external causes; the one form is as natural to it as the other, but it will always show the same form in the same circumstances; it is equally ready for any, but in every case true to its character, and at all times revealing this alone. So will every human character under all circumstances reveal itself, but the

phenomena which proceed from it will always be in accordance with the circumstances.

§ 27. If, from the foregoing consideration of the forces of nature and their phenomena, we have come to see clearly how far an explanation from causes can go, and where it must stop if it is not to degenerate into the vain attempt to reduce the content of all phenomena to their mere form, in which case there would ultimately remain nothing but form, we shall be able to settle in general terms what is to be demanded of etiology as a whole. It must seek out the causes of all phenomena in nature, *i.e.*, the circumstances under which they invariably appear. Then it must refer the multitude of phenomena which have various forms in various circumstances to what is active in every phenomenon, and is presupposed in the cause, — original forces of nature. It must correctly distinguish between a difference of the phenomenon which arises from a difference of the force, and one which results merely from a difference of the circumstances under which the force expresses itself; and with equal care it must guard against taking the expressions of one and the same force under different circumstances for the manifestations of different forces, and conversely against taking for manifestations of one and the same force what originally belongs to different forces. Now this is the direct work of the faculty of judgment, and that is why so few men are capable of increasing our insight in physics, while all are able to enlarge experience. Indolence and ignorance make us disposed to appeal too soon to original forces. This is exemplified with an exaggeration that savours of irony in the entities and quidities of the schoolmen. Nothing is further from my desire than to favour their resuscitation. We have just as little right to appeal to the objectification of will, instead of giving a physical explanation, as we have to appeal to the creative power of God. For physics demands causes, and the will is never a cause. Its whole relation to the phenomenon is not in accordance with the principle of sufficient reason. But that which in itself is the will exists in another aspect as idea; that is to say, is phenomenon. As such, it obeys the laws which constitute the form of the phenomenon. Every movement, for example, although it is always a manifestation of will, must yet have a cause from which it is to be explained in relation to a particular time and space; that is, not in general in its inner nature, but as a *particular* phenomenon. In the case of the stone, this is a mechanical cause; in that of the movement of a man, it is a motive; but in no case can it be wanting. On

the other hand, the universal common nature of all phenomena of one particular kind, that which must be presupposed if the explanation from causes is to have any sense and meaning, is the general force of nature, which, in physics, must remain a *qualitas occulta*, because with it the etiological explanation ends and the metaphysical begins. But the chain of causes and effects is never broken by an original force to which it has been necessary to appeal. It does not run back to such a force as if it were its first link, but the nearest link, as well as the remotest, presupposes the original force, and could otherwise explain nothing. A series of causes and effects may be the manifestation of the most different kinds of forces, whose successive visible appearances are conducted through it, as I have illustrated above by the example of a metal machine. But the difference of these original forces, which cannot be referred to each other, by no means breaks the unity of that chain of causes, and the connection between all its links. The etiology and the philosophy of nature never do violence to each other, but go hand in hand, regarding the same object from different points of view. Etiology gives an account of the causes which necessarily produce the particular phenomenon to be explained. It exhibits, as the foundation of all its explanations, the universal forces which are active in all these causes and effects. It accurately defines, enumerates, and distinguishes these forces, and then indicates all the different effects in which each force appears, regulated by the difference of the circumstances, always in accordance with its own peculiar character, which it discloses in obedience to an invariable rule, called *a law of nature*. When all this has been thoroughly accomplished by physics in every particular, it will be complete, and its work will be done. There will then remain no unknown force in unorganised nature, nor any effect, which has not been proved to be the manifestation of one of these forces under definite circumstances, in accordance with a law of nature. Yet a law of nature remains merely the observed rule according to which nature invariably proceeds whenever certain definite circumstances occur. Therefore a law of nature may be defined as a fact expressed generally — *un fait généralisé* — and thus a complete enumeration of all the laws of nature would only be a complete register of facts. The consideration of nature as a whole is thus completed in *morphology*, which enumerates, compares, and arranges all the enduring forms of organised nature. Of the causes of the appearance of the individual creature it has little to say, for in all cases this is procreation (the theory of

which is a separate matter), and in rare cases the *generatio æquivoca*. But to this last belongs, strictly speaking, the manner in which all the lower grades of the objectification of will, that is to say, physical and chemical phenomena, appear as individual, and it is precisely the task of etiology to point out the conditions of this appearance. Philosophy, on the other hand, concerns itself only with the universal, in nature as everywhere else. The original forces themselves are here its object, and it recognises in them the different grades of the objectivity of will, which is the inner nature, the "in-itself" of this world; and when it regards the world apart from will, it explains it as merely the idea of the subject. But if etiology, instead of preparing the way for philosophy, and supplying its doctrines with practical application by means of instances, supposes that its aim is rather to deny the existence of all original forces, except perhaps *one*, the most general, for example, impenetrability, which it imagines it thoroughly understands, and consequently seeks forcibly to refer all the others to it — it forsakes its own province and can only give us error instead of truth. The content of nature is supplanted by its form, everything is ascribed to the circumstances which work from without, and nothing to the inner nature of the thing. Now if it were possible to succeed by this method, a problem in arithmetic would ultimately, as we have already remarked, solve the riddle of the universe. But this is the method adopted by those, referred to above, who think that all physiological effects ought to be reduced to form and combination, this, perhaps, to electricity, and this again to chemism, and chemism to mechanism. The mistake of Descartes, for example, and of all the Atomists, was of this last description. They referred the movements of the globe to the impact of a fluid, and the qualities of matter to the connection and form of the atoms, and hence they laboured to explain all the phenomena of nature as merely manifestations of impenetrability and cohesion. Although this has been given up, precisely the same error is committed in our own day by the electrical, chemical, and mechanical physiologists, who obstinately attempt to explain the whole of life and all the functions of the organism from "form and combination." In Meckel's "Archiv für Physiologie" (1820, vol. v. p. 185) we still find it stated that the aim of physiological explanation is the reduction of organic life to the universal forces with which physics deals. Lamarck also, in his "*Philosophie Zoologique*," explains life as merely the effect of warmth and electricity: *le calorique et la matière électrique suffisent parfaitement pour composer ensemble cette*

cause essentielle de la vie (p. 16). According to this, warmth and electricity would be the "thing-in-itself," and the world of animals and plants its phenomenal appearance. The absurdity of this opinion becomes glaringly apparent at the 306th and following pages of that work. It is well known that all these opinions, that have been so often refuted, have reappeared quite recently with renewed confidence. If we carefully examine the foundation of these views, we shall find that they ultimately involve the presupposition that the organism is merely an aggregate of phenomena of physical, chemical, and mechanical forces, which have come together here by chance, and produced the organism as a freak of nature without further significance. The organism of an animal or of a human being would therefore be, if considered philosophically, not the exhibition of a special Idea, that is, not itself immediate objectivity of the will at a definite higher grade, but in it would appear only those Ideas which objectify the will in electricity, in chemism, and in mechanism. Thus the organism would be as fortuitously constructed by the concurrence of these forces as the forms of men and beasts in clouds and stalactites, and would therefore in itself be no more interesting than they are. However, we shall see immediately how far the application of physical and chemical modes of explanation to the organism may yet, within certain limits, be allowable and useful; for I shall explain that the vital force certainly avails itself of and uses the forces of unorganised nature; yet these forces no more constitute the vital force than a hammer and anvil make a blacksmith. Therefore even the most simple example of plant life can never be explained from these forces by any theory of capillary attraction and endosmose, much less animal life. The following observations will prepare the way for this somewhat difficult discussion.

It follows from all that has been said that it is certainly an error on the part of natural science to seek to refer the higher grades of the objectification of will to the lower; for the failure to recognise, or the denial of, original and self-existing forces of nature is just as wrong as the groundless assumption of special forces when what occurs is merely a peculiar kind of manifestation of what is already known. Thus Kant rightly says that it would be absurd to hope for a blade of grass from a Newton, that is, from one who reduced the blade of grass to the manifestations of physical and chemical forces, of which it was the chance product, and therefore a mere freak of nature, in which no special Idea appeared, *i.e.*, the

will did not directly reveal itself in it in a higher and specific grade, but just as in the phenomena of unorganised nature and by chance in this form. The schoolmen, who certainly would not have allowed such a doctrine, would rightly have said that it was a complete denial of the *forma substantialis*, and a degradation of it to the *forma accidentalis*. For the *forma substantialis* of Aristotle denotes exactly what I call the grade of the objectification of will in a thing. On the other hand, it is not to be overlooked that in all Ideas, that is, in all forces of unorganised, and all forms of organised nature, it is *one and the same* will that reveals itself, that is to say, which enters the form of the idea and passes into *objectivity*. Its unity must therefore be also recognisable through an inner relationship between all its phenomena. Now this reveals itself in the higher grades of the objectification of will, where the whole phenomenon is more distinct, thus in the vegetable and animal kingdoms, through the universally prevailing analogy of all forms, the fundamental type which recurs in all phenomena. This has, therefore, become the guiding principle of the admirable zoological system which was originated by the French in this century, and it is most completely established in comparative anatomy as *l'unité de plan*, *l'uniformité de l'élément anatomique*. To discover this fundamental type has been the chief concern, or at any rate the praiseworthy endeavour, of the natural philosophers of the school of Schelling, who have in this respect considerable merit, although in many cases their hunt after analogies in nature degenerated into mere conceits. They have, however, rightly shown that that general relationship and family likeness exists also in the Ideas of unorganised nature; for example, between electricity and magnetism, the identity of which was afterwards established; between chemical attraction and gravitation, and so forth. They specially called attention to the fact that *polarity*, that is, the sundering of a force into two qualitatively different and opposed activities striving after reunion, which also shows itself for the most part in space as a dispersion in opposite directions, is a fundamental type of almost all the phenomena of nature, from the magnet and the crystal to man himself. Yet this knowledge has been current in China from the earliest times, in the doctrine of opposition of Yin and Yang. Indeed, since all things in the world are the objectification of one and the same will, and therefore in their inner nature identical, it must not only be the case that there is that unmistakable analogy between them, and that in every phenomenon the trace, intimation, and plan of the higher phenomenon that

lies next to it in point of development shows itself, but also because all these forms belong to the world as *idea*, it is indeed conceivable that even in the most universal forms of the idea, in that peculiar framework of the phenomenal world space and time, it may be possible to discern and establish the fundamental type, intimation, and plan of what fills the forms. It seems to have been a dim notion of this that was the origin of the Cabala and all the mathematical philosophy of the Pythagoreans, and also of the Chinese in Y-king. In the school of Schelling also, to which we have already referred, we find, among their efforts to bring to light the similarity among the phenomena of nature, several attempts (though rather unfortunate ones) to deduce laws of nature from the laws of pure space and time. However, one can never tell to what extent a man of genius will realise both endeavours.

Now, although the difference between phenomenon and thing-in-itself is never lost sight of, and therefore the identity of the will which objectifies itself in all Ideas can never (because it has different grades of its objectification) be distorted to mean identity of the particular Ideas themselves in which it appears, so that, for example, chemical or electrical attraction can never be reduced to the attraction of gravitation, although this inner analogy is known, and the former may be regarded as, so to speak, higher powers of the latter, just as little does the similarity of the construction of all animals warrant us in mixing and identifying the species and explaining the more developed as mere variations of the less developed; and although, finally, the physiological functions are never to be reduced to chemical or physical processes, yet, in justification of this procedure, within certain limits, we may accept the following observations as highly probable.

If several of the phenomena of will in the lower grades of its objectification — that is, in unorganised nature — come into conflict because each of them, under the guidance of causality, seeks to possess a given portion of matter, there arises from the conflict the phenomenon of a higher Idea which prevails over all the less developed phenomena previously there, yet in such a way that it allows the essence of these to continue to exist in a subordinate manner, in that it takes up into itself from them something which is analogous to them. This process is only intelligible from the identity of the will which manifests itself in all the Ideas, and which is always striving after higher objectification. We thus see, for example, in the hardening of the bones, an unmistakable analogy to

crystallisation, as the force which originally had possession of the chalk, although ossification is never to be reduced to crystallisation. The analogy shows itself in a weaker degree in the flesh becoming firm. The combination of humours in the animal body and secretion are also analogous to chemical combination and separation. Indeed, the laws of chemistry are still strongly operative in this case, but subordinated, very much modified, and mastered by a higher Idea; therefore mere chemical forces outside the organism will never afford us such humours; but

"Encheiresin naturæ nennt es die Chemie,
Spottet ihrer selbst und weiss nicht wie."

The more developed Idea resulting from this victory over several lower Ideas or objectifications of will, gains an entirely new character by taking up into itself from every Idea over which it has prevailed a strengthened analogy. The will objectifies itself in a new, more distinct way. It originally appears in *generatio æquivoca*; afterwards in assimilation to the given germ, organic moisture, plant, animal, man. Thus from the strife of lower phenomena the higher arise, swallowing them all up, but yet realising in the higher grade the tendency of all the lower. Here, then, already the law applies — *Serpens nisi serpentem comederit non fit draco.*

I wish it had been possible for me to dispel by clearness of explanation the obscurity which clings to the subject of these thoughts; but I see very well that the reader's own consideration of the matter must materially aid me if I am not to remain uncomprehended or misunderstood. According to the view I have expressed, the traces of chemical and physical modes of operation will indeed be found in the organism, but it can never be explained from them; because it is by no means a phenomenon even accidentally brought about through the united actions of such forces, but a higher Idea which has overcome these lower ideas by *subduing assimilation*; for the *one* will which objectifies itself in all Ideas always seeks the highest possible objectification, and has therefore in this case given up the lower grades of its manifestation after a conflict, in order to appear in a higher grade, and one so much the more powerful. No victory without conflict: since the higher Idea or objectification of will can only appear through the conquest of the lower, it endures the opposition of these lower Ideas, which, although brought into subjection, still constantly strive to obtain an independent and complete expression of their being. The

magnet that has attracted a piece of iron carries on a perpetual conflict with gravitation, which, as the lower objectification of will, has a prior right to the matter of the iron; and in this constant battle the magnet indeed grows stronger, for the opposition excites it, as it were, to greater effort. In the same way every manifestation of the will, including that which expresses itself in the human organism, wages a constant war against the many physical and chemical forces which, as lower Ideas, have a prior right to that matter. Thus the arm falls which for a while, overcoming gravity, we have held stretched out; thus the pleasing sensation of health, which proclaims the victory of the Idea of the self-conscious organism over the physical and chemical laws, which originally governed the humours of the body, is so often interrupted, and is indeed always accompanied by greater or less discomfort, which arises from the resistance of these forces, and on account of which the vegetative part of our life is constantly attended by slight pain. Thus also digestion weakens all the animal functions, because it requires the whole vital force to overcome the chemical forces of nature by assimilation. Hence also in general the burden of physical life, the necessity of sleep, and, finally, of death; for at last these subdued forces of nature, assisted by circumstances, win back from the organism, wearied even by the constant victory, the matter it took from them, and attain to an unimpeded expression of their being. We may therefore say that every organism expresses the Idea of which it is the image, only after we have subtracted the part of its force which is expended in subduing the lower Ideas that strive with it for matter. This seems to have been running in the mind of Jacob Böhm when he says somewhere that all the bodies of men and animals, and even all plants, are really half dead. According as the subjection in the organism of these forces of nature, which express the lower grades of the objectification of will, is more or less successful, the more or the less completely does it attain to the expression of its Idea; that is to say, the nearer it is to the *ideal* or the further from it — the *ideal* of beauty in its species.

Thus everywhere in nature we see strife, conflict, and alternation of victory, and in it we shall come to recognise more distinctly that variance with itself which is essential to the will. Every grade of the objectification of will fights for the matter, the space, and the time of the others. The permanent matter must constantly change its form; for under the guidance of causality, mechanical, physical, chemical, and organic phenomena,

eagerly striving to appear, wrest the matter from each other, for each desires to reveal its own Idea. This strife may be followed through the whole of nature; indeed nature exists only through it: ει γαρ μη ην το νεικος εν τοις πραγμασιν, ἑν αν ην ἁπαντα, ὡς φησιν Εμπεδοκλης; (nam si non inesset in rebus contentio, unum omnia essent, ut ait Empedocles. Aris. Metaph., B. 5). Yet this strife itself is only the revelation of that variance with itself which is essential to the will. This universal conflict becomes most distinctly visible in the animal kingdom. For animals have the whole of the vegetable kingdom for their food, and even within the animal kingdom every beast is the prey and the food of another; that is, the matter in which its Idea expresses itself must yield itself to the expression of another Idea, for each animal can only maintain its existence by the constant destruction of some other. Thus the will to live everywhere preys upon itself, and in different forms is its own nourishment, till finally the human race, because it subdues all the others, regards nature as a manufactory for its use. Yet even the human race, as we shall see in the Fourth Book, reveals in itself with most terrible distinctness this conflict, this variance with itself of the will, and we find *homo homini lupus*. Meanwhile we can recognise this strife, this subjugation, just as well in the lower grades of the objectification of will. Many insects (especially ichneumon-flies) lay their eggs on the skin, and even in the body of the larvæ of other insects, whose slow destruction is the first work of the newly hatched brood. The young hydra, which grows like a bud out of the old one, and afterwards separates itself from it, fights while it is still joined to the old one for the prey that offers itself, so that the one snatches it out of the mouth of the other (Trembley, Polypod., ii. p. 110, and iii. p. 165). But the bulldog-ant of Australia affords us the most extraordinary example of this kind; for if it is cut in two, a battle begins between the head and the tail. The head seizes the tail with its teeth, and the tail defends itself bravely by stinging the head: the battle may last for half an hour, until they die or are dragged away by other ants. This contest takes place every time the experiment is tried. (From a letter by Howitt in the W. Journal, reprinted in Galignani's Messenger, 17th November 1855.) On the banks of the Missouri one sometimes sees a mighty oak the stem and branches of which are so encircled, fettered, and interlaced by a gigantic wild vine, that it withers as if choked. The same thing shows itself in the lowest grades; for example, when water and carbon are changed into vegetable sap, or vegetables or bread into blood by organic

assimilation; and so also in every case in which animal secretion takes place, along with the restriction of chemical forces to a subordinate mode of activity. This also occurs in unorganised nature, when, for example, crystals in process of formation meet, cross, and mutually disturb each other to such an extent that they are unable to assume the pure crystalline form, so that almost every cluster of crystals is an image of such a conflict of will at this low grade of its objectification; or again, when a magnet forces its magnetism upon iron, in order to express its Idea in it; or when galvanism overcomes chemical affinity, decomposes the closest combinations, and so entirely suspends the laws of chemistry that the acid of a decomposed salt at the negative pole must pass to the positive pole without combining with the alkalies through which it goes on its way, or turning red the litmus paper that touches it. On a large scale it shows itself in the relation between the central body and the planet, for although the planet is in absolute dependence, yet it always resists, just like the chemical forces in the organism; hence arises the constant tension between centripetal and centrifugal force, which keeps the globe in motion, and is itself an example of that universal essential conflict of the manifestation of will which we are considering. For as every body must be regarded as the manifestation of a will, and as will necessarily expresses itself as a struggle, the original condition of every world that is formed into a globe cannot be rest, but motion, a striving forward in boundless space without rest and without end. Neither the law of inertia nor that of causality is opposed to this: for as, according to the former, matter as such is alike indifferent to rest and motion, its original condition may just as well be the one as the other, therefore if we first find it in motion, we have just as little right to assume that this was preceded by a condition of rest, and to inquire into the cause of the origin of the motion, as, conversely, if we found it at rest, we would have to assume a previous motion and inquire into the cause of its suspension. It is, therefore, not needful to seek for a first impulse for centrifugal force, for, according to the hypothesis of Kant and Laplace, it is, in the case of the planets, the residue of the original rotation of the central body, from which the planets have separated themselves as it contracted. But to this central body itself motion is essential; it always continues its rotation, and at the same time rushes forward in endless space, or perhaps circulates round a greater central body invisible to us. This view entirely agrees with the conjecture of astronomers that there is a central sun, and

also with the observed advance of our whole solar system, and perhaps of the whole stellar system to which our sun belongs. From this we are finally led to assume a general advance of fixed stars, together with the central sun, and this certainly loses all meaning in boundless space (for motion in absolute space cannot be distinguished from rest), and becomes, as is already the case from its striving and aimless flight, an expression of that nothingness, that failure of all aim, which, at the close of this book, we shall be obliged to recognise in the striving of will in all its phenomena. Thus boundless space and endless time must be the most universal and essential forms of the collective phenomena of will, which exist for the expression of its whole being. Lastly, we can recognise that conflict which we are considering of all phenomena of will against each other in simple matter regarded as such; for the real characteristic of matter is correctly expressed by Kant as repulsive and attractive force; so that even crude matter has its existence only in the strife of conflicting forces. If we abstract from all chemical differences in matter, or go so far back in the chain of causes and effects that as yet there is no chemical difference, there remains mere matter, — the world rounded to a globe, whose life, *i.e.*, objectification of will, is now constituted by the conflict between attractive and repulsive forces, the former as gravitation pressing from all sides towards the centre, the latter as impenetrability always opposing the former either as rigidity or elasticity; and this constant pressure and resistance may be regarded as the objectivity of will in its very lowest grade, and even there it expresses its character.

We should see the will express itself here in the lowest grade as blind striving, an obscure, inarticulate impulse, far from susceptible of being directly known. It is the simplest and the weakest mode of its objectification. But it appears as this blind and unconscious striving in the whole of unorganised nature, in all those original forces of which it is the work of physics and chemistry to discover and to study the laws, and each of which manifests itself to us in millions of phenomena which are exactly similar and regular, and show no trace of individual character, but are mere multiplicity through space and time, *i.e.*, through the *principium individuationis*, as a picture is multiplied through the facets of a glass.

From grade to grade objectifying itself more distinctly, yet still completely without consciousness as an obscure striving force, the will acts in the vegetable kingdom also, in which the bond of its phenomena consists

no longer properly of causes, but of stimuli; and, finally, also in the vegetative part of the animal phenomenon, in the production and maturing of the animal, and in sustaining its inner economy, in which the manifestation of will is still always necessarily determined by stimuli. The ever-ascending grades of the objectification of will bring us at last to the point at which the individual that expresses the Idea could no longer receive food for its assimilation through mere movement following upon stimuli. For such a stimulus must be waited for, but the food has now come to be of a more special and definite kind, and with the ever-increasing multiplicity of the individual phenomena, the crowd and confusion has become so great that they interfere with each other, and the chance of the individual that is moved merely by stimuli and must wait for its food would be too unfavourable. From the point, therefore, at which the animal has delivered itself from the egg or the womb in which it vegetated without consciousness, its food must be sought out and selected. For this purpose movement following upon motives, and therefore consciousness, becomes necessary, and consequently it appears as an agent, μηχανη, called in at this stage of the objectification of will for the conservation of the individual and the propagation of the species. It appears represented by the brain or a large ganglion, just as every other effort or determination of the will which objectifies itself is represented by an organ, that is to say, manifests itself for the idea as an organ.[36] But with this means of assistance, this μηχανη, the *world as idea* comes into existence at a stroke, with all its forms, object and subject, time, space, multiplicity, and causality. The world now shows its second side. Till now *mere will*, it becomes also *idea*, object of the knowing subject. The will, which up to this point followed its tendency in the dark with unerring certainty, has at this grade kindled for itself a light as a means which became necessary for getting rid of the disadvantage which arose from the throng and the complicated nature of its manifestations, and which would have accrued precisely to the most perfect of them. The hitherto infallible certainty and regularity with which it worked in unorganised and merely vegetative nature, rested upon the fact that it alone was active in its original nature, as blind impulse, will, without assistance, and also without interruption, from a second and entirely different world, the world as idea, which is indeed only the image of its own inner being, but is yet of quite another nature, and now encroaches on the connected whole of its phenomena. Hence its infallible certainty comes to an end.

Animals are already exposed to illusion, to deception. They have, however, merely ideas of perception, no conceptions, no reflection, and they are therefore bound to the present; they cannot have regard for the future. It seems as if this knowledge without reason was not in all cases sufficient for its end, and at times required, as it were, some assistance. For the very remarkable phenomenon presents itself, that the blind working of the will and the activity enlightened by knowledge encroach in a most astonishing manner upon each other's spheres in two kinds of phenomena. In the one case we find in the very midst of those actions of animals which are guided by perceptive knowledge and its motives one kind of action which is accomplished apart from these, and thus through the necessity of the blindly acting will. I refer to those mechanical instincts which are guided by no motive or knowledge, and which yet have the appearance of performing their work from abstract rational motives. The other case, which is opposed to this, is that in which, on the contrary, the light of knowledge penetrates into the workshop of the blindly active will, and illuminates the vegetative functions of the human organism. I mean clairvoyance. Finally, when the will has attained to the highest grade of its objectification, that knowledge of the understanding given to brutes to which the senses supply the data, out of which there arises mere perception confined to what is immediately present, does not suffice. That complicated, many-sided, imaginative being, man, with his many needs, and exposed as he is to innumerable dangers, must, in order to exist, be lighted by a double knowledge; a higher power, as it were, of perceptive knowledge must be given him, and also reason, as the faculty of framing abstract conceptions. With this there has appeared reflection, surveying the future and the past, and, as a consequence, deliberation, care, the power of premeditated action independent of the present, and finally, the full and distinct consciousness of one's own deliberate volition as such. Now if with mere knowledge of perception there arose the possibility of illusion and deception, by which the previous infallibility of the blind striving of will was done away with, so that mechanical and other instincts, as expressions of unconscious will, had to lend their help in the midst of those that were conscious, with the entrance of reason that certainty and infallibility of the expressions of will (which at the other extreme in unorganised nature appeared as strict conformity to law) is almost entirely lost; instinct disappears altogether; deliberation, which is supposed to take the place of everything else, begets (as was

shown in the First Book) irresolution and uncertainty; then error becomes possible, and in many cases obstructs the adequate objectification of the will in action. For although in the character the will has already taken its definite and unchangeable bent or direction, in accordance with which volition, when occasioned by the presence of a motive, invariably takes place, yet error can falsify its expressions, for it introduces illusive motives that take the place of the real ones which they resemble;[37] as, for example, when superstition forces on a man imaginary motives which impel him to a course of action directly opposed to the way in which the will would otherwise express itself in the given circumstances. Agamemnon slays his daughter; a miser dispenses alms, out of pure egotism, in the hope that he will some day receive an hundred-fold; and so on.

Thus knowledge generally, rational as well as merely sensuous, proceeds originally from the will itself, belongs to the inner being of the higher grades of its objectification as a mere μηχανη, a means of supporting the individual and the species, just like any organ of the body. Originally destined for the service of the will for the accomplishment of its aims, it remains almost throughout entirely subjected to its service: it is so in all brutes and in almost all men. Yet we shall see in the Third Book how in certain individual men knowledge can deliver itself from this bondage, throw off its yoke, and, free from all the aims of will, exist purely for itself, simply as a clear mirror of the world, which is the source of art. Finally, in the Fourth Book, we shall see how, if this kind of knowledge reacts on the will, it can bring about self-surrender, *i.e.*, resignation, which is the final goal, and indeed the inmost nature of all virtue and holiness, and is deliverance from the world.

§ 28. We have considered the great multiplicity and diversity of the phenomena in which the will objectifies itself, and we have seen their endless and implacable strife with each other. Yet, according to the whole discussion up to this point, the will itself, as thing-in-itself, is by no means included in that multiplicity and change. The diversity of the (Platonic) Ideas, *i.e.*, grades of objectification, the multitude of individuals in which each of these expresses itself, the struggle of forms for matter, — all this does not concern it, but is only the manner of its objectification, and only through this has an indirect relation to it, by virtue of which it belongs to the expression of the nature of will for the idea. As the magic-lantern shows many different pictures, which are all made visible by one and the same

light, so in all the multifarious phenomena which fill the world together or throng after each other as events, only *one will* manifests itself, of which everything is the visibility, the objectivity, and which remains unmoved in the midst of this change; it alone is thing-in-itself; all objects are manifestations, or, to speak the language of Kant, phenomena. Although in man, as (Platonic) Idea, the will finds its clearest and fullest objectification, yet man alone could not express its being. In order to manifest the full significance of the will, the Idea of man would need to appear, not alone and sundered from everything else, but accompanied by the whole series of grades, down through all the forms of animals, through the vegetable kingdom to unorganised nature. All these supplement each other in the complete objectification of will; they are as much presupposed by the Idea of man as the blossoms of a tree presuppose leaves, branches, stem, and root; they form a pyramid, of which man is the apex. If fond of similes, one might also say that their manifestations accompany that of man as necessarily as the full daylight is accompanied by all the gradations of twilight, through which, little by little, it loses itself in darkness; or one might call them the echo of man, and say: Animal and plant are the descending fifth and third of man, the inorganic kingdom is the lower octave. The full truth of this last comparison will only become clear to us when, in the following book, we attempt to fathom the deep significance of music, and see how a connected, progressive melody, made up of high, quick notes, may be regarded as in some sense expressing the life and efforts of man connected by reflection, while the unconnected complemental notes and the slow bass, which make up the harmony necessary to perfect the music, represent the rest of the animal kingdom and the whole of nature that is without knowledge. But of this in its own place, where it will not sound so paradoxical. We find, however, that the *inner necessity* of the gradation of its manifestations, which is inseparable from the adequate objectification of the will, is expressed by an *outer necessity* in the whole of these manifestations themselves, by reason of which man has need of the beasts for his support, the beasts in their grades have need of each other as well as of plants, which in their turn require the ground, water, chemical elements and their combinations, the planet, the sun, rotation and motion round the sun, the curve of the ellipse, &c., &c. At bottom this results from the fact that the will must live on itself, for there exists nothing

beside it, and it is a hungry will. Hence arise eager pursuit, anxiety, and suffering.

It is only the knowledge of the unity of will as thing-in-itself, in the endless diversity and multiplicity of the phenomena, that can afford us the true explanation of that wonderful, unmistakable analogy of all the productions of nature, that family likeness on account of which we may regard them as variations on the same ungiven theme. So in like measure, through the distinct and thoroughly comprehended knowledge of that harmony, that essential connection of all the parts of the world, that necessity of their gradation which we have just been considering, we shall obtain a true and sufficient insight into the inner nature and meaning of the undeniable *teleology* of all organised productions of nature, which, indeed, we presupposed *a priori*, when considering and investigating them.

This *teleology* is of a twofold description; sometimes an *inner teleology*, that is, an agreement of all the parts of a particular organism, so ordered that the sustenance of the individual and the species results from it, and therefore presents itself as the end of that disposition or arrangement. Sometimes, however, there is an *outward teleology*, a relation of unorganised to organised nature in general, or of particular parts of organised nature to each other, which makes the maintenance of the whole of organised nature, or of the particular animal species, possible, and therefore presents itself to our judgment as the means to this end.

Inner teleology is connected with the scheme of our work in the following way. If, in accordance with what has been said, all variations of form in nature, and all multiplicity of individuals, belong not to the will itself, but merely to its objectivity and the form of this objectivity, it necessarily follows that the will is indivisible and is present as a whole in every manifestation, although the grades of its objectification, the (Platonic) Ideas, are very different from each other. We may, for the sake of simplicity, regard these different Ideas as in themselves individual and simple acts of the will, in which it expresses its nature more or less. Individuals, however, are again manifestations of the Ideas, thus of these acts, in time, space, and multiplicity. Now, in the lowest grades of objectivity, such an act (or an Idea) retains its unity in the manifestation; while, in order to appear in higher grades, it requires a whole series of conditions and developments in time, which only collectively express its nature completely. Thus, for example the Idea that reveals itself in any general force of nature has

always one single expression, although it presents itself differently according to the external relations that are present: otherwise its identity could not be proved, for this is done by abstracting the diversity that arises merely from external relations. In the same way the crystal has only *one* manifestation of life, crystallisation, which afterwards has its fully adequate and exhaustive expression in the rigid form, the corpse of that momentary life. The plant, however, does not express the Idea, whose phenomenon it is, at once and through a single manifestation, but in a succession of developments of its organs in time. The animal not only develops its organism in the same manner, in a succession of forms which are often very different (metamorphosis), but this form itself, although it is already objectivity of will at this grade, does not attain to a full expression of its Idea. This expression must be completed through the actions of the animal, in which its empirical character, common to the whole species, manifests itself, and only then does it become the full revelation of the Idea, a revelation which presupposes the particular organism as its first condition. In the case of man, the empirical character is peculiar to every individual (indeed, as we shall see in the Fourth Book, even to the extent of supplanting entirely the character of the species, through the self-surrender of the whole will). That which is known as the empirical character, through the necessary development in time, and the division into particular actions that is conditioned by it, is, when we abstract from this temporal form of the manifestation the *intelligible character*, according to the expression of Kant, who shows his undying merit especially in establishing this distinction and explaining the relation between freedom and necessity, *i.e.*, between the will as thing-in-itself and its manifestations in time.[38] Thus the intelligible character coincides with the Idea, or, more accurately, with the original act of will which reveals itself in it. So far then, not only the empirical character of every man, but also that of every species of animal and plant, and even of every original force of unorganised nature, is to be regarded as the manifestation of an intelligible character, that is, of a timeless, indivisible act of will. I should like here to draw attention in passing to the naïveté with which every plant expresses and lays open its whole character in its mere form, reveals its whole being and will. This is why the physiognomy of plants is so interesting; while in order to know an animal in its Idea, it is necessary to observe the course of its action. As for man, he must be fully investigated and tested, for reason makes him capable

of a high degree of dissimulation. The beast is as much more naïve than the man as the plant is more naïve than the beast. In the beast we see the will to live more naked, as it were, than in the man, in whom it is clothed with so much knowledge, and is, moreover, so veiled through the capacity for dissimulation, that it is almost only by chance, and here and there, that its true nature becomes apparent. In the plant it shows itself quite naked, but also much weaker, as mere blind striving for existence without end or aim. For the plant reveals its whole being at the first glance, and with complete innocence, which does not suffer from the fact that it carries its organs of generation exposed to view on its upper surface, though in all animals they have been assigned to the most hidden part. This innocence of the plant results from its complete want of knowledge. Guilt does not lie in willing, but in willing with knowledge. Every plant speaks to us first of all of its home, of the climate, and the nature of the ground in which it has grown. Therefore, even those who have had little practice easily tell whether an exotic plant belongs to the tropical or the temperate zone, and whether it grows in water, in marshes, on mountain, or on moorland. Besides this, however, every plant expresses the special will of its species, and says something that cannot be uttered in any other tongue. But we must now apply what has been said to the teleological consideration of the organism, so far as it concerns its inner design. If in unorganised nature the Idea, which is everywhere to be regarded as a single act of will, reveals itself also in a single manifestation which is always the same, and thus one may say that here the empirical character directly partakes of the unity of the intelligible, coincides, as it were, with it, so that no inner design can show itself here; if, on the contrary, all organisms express their Ideas through a series of successive developments, conditioned by a multiplicity of co-existing parts, and thus only the sum of the manifestations of the empirical character collectively constitute the expression of the intelligible character; this necessary co-existence of the parts and succession of the stages of development does not destroy the unity of the appearing Idea, the act of will which expresses itself; nay, rather this unity finds its expression in the necessary relation and connection of the parts and stages of development with each other, in accordance with the law of causality. Since it is the will which is one, indivisible, and therefore entirely in harmony with itself, that reveals itself in the whole Idea as in act, its manifestation, although broken up into a number of different parts and conditions, must yet show this unity

again in the thorough agreement of all of these. This is effected by a necessary relation and dependence of all the parts upon each other, by means of which the unity of the Idea is re-established in the manifestation. In accordance with this, we now recognise these different parts and functions of the organism as related to each other reciprocally as means and end, but the organism itself as the final end of all. Consequently, neither the breaking up of the Idea, which in itself is simple, into the multiplicity of the parts and conditions of the organism, on the one hand, nor, on the other hand, the re-establishment of its unity through the necessary connection of the parts and functions which arises from the fact that they are the cause and effect, the means and end, of each other, is peculiar and essential to the appearing will as such, to the thing-in-itself, but only to its manifestation in space, time, and causality (mere modes of the principle of sufficient reason, the form of the phenomenon). They belong to the world as idea, not to the world as will; they belong to the way in which the will becomes object, *i.e.*, idea at this grade of its objectivity. Every one who has grasped the meaning of this discussion — a discussion which is perhaps somewhat difficult — will now fully understand the doctrine of Kant, which follows from it, that both the design of organised and the conformity to law of unorganised nature are only introduced by our understanding, and therefore both belong only to the phenomenon, not to the thing-in-itself. The surprise, which was referred to above, at the infallible constancy of the conformity to law of unorganised nature, is essentially the same as the surprise that is excited by design in organised nature; for in both cases what we wonder at is only the sight of the original unity of the Idea, which, for the phenomenon, has assumed the form of multiplicity and diversity.[39]

As regards the second kind of teleology, according to the division made above, the *outer* design, which shows itself, not in the inner economy of the organisms, but in the support and assistance they receive from without, both from unorganised nature and from each other; its general explanation is to be found in the exposition we have just given. For the whole world, with all its phenomena, is the objectivity of the one indivisible will, the Idea, which is related to all other Ideas as harmony is related to the single voice. Therefore that unity of the will must show itself also in the agreement of all its manifestations. But we can very much increase the clearness of this insight if we go somewhat more closely into the manifestations of that outer teleology and agreement of the different parts of nature with each other, an

inquiry which will also throw some light on the foregoing exposition. We shall best attain this end by considering the following analogy.

The character of each individual man, so far as it is thoroughly individual, and not entirely included in that of the species, may be regarded as a special Idea, corresponding to a special act of the objectification of will. This act itself would then be his intelligible character, and his empirical character would be the manifestation of it. The empirical character is entirely determined through the intelligible, which is without ground, *i.e.*, as thing-in-itself is not subordinated to the principle of sufficient reason (the form of the phenomenon). The empirical character must in the course of life afford us the express image of the intelligible, and can only become what the nature of the latter demands. But this property extends only to the essential, not to the unessential in the course of life to which it applies. To this unessential belong the detailed events and actions which are the material in which the empirical character shows itself. These are determined by outward circumstances, which present the motives upon which the character reacts according to its nature; and as they may be very different, the outward form of the manifestation of the empirical character, that is, the definite actual or historical form of the course of life, will have to accommodate itself to their influence. Now this form may be very different, although what is essential to the manifestation, its content, remains the same. Thus, for example it is immaterial whether a man plays for nuts or for crowns; but whether a man cheats or plays fairly, that is the real matter; the latter is determined by the intelligible character, the former by outward circumstances. As the same theme may be expressed in a hundred different variations, so the same character may be expressed in a hundred very different lives. But various as the outward influence may be, the empirical character which expresses itself in the course of life must yet, whatever form it takes, accurately objectify the intelligible character, for the latter adapts its objectification to the given material of actual circumstances. We have now to assume something analogous to the influence of outward circumstances upon the life that is determined in essential matters by the character, if we desire to understand how the will, in the original act of its objectification, determines the various Ideas in which it objectifies itself, that is, the different forms of natural existence of every kind, among which it distributes its objectification, and which must therefore necessarily have a relation to each other in the manifestation. We must assume that between all

these manifestations of the *one* will there existed a universal and reciprocal adaptation and accommodation of themselves to each other, by which, however, as we shall soon see more clearly, all time-determination is to be excluded, for the Idea lies outside time. In accordance with this, every manifestation must have adapted itself to the surroundings into which it entered, and these again must have adapted themselves to it, although it occupied a much later position in time; and we see this *consensus naturæ* everywhere. Every plant is therefore adapted to its soil and climate, every animal to its element and the prey that will be its food, and is also in some way protected, to a certain extent, against its natural enemy: the eye is adapted to the light and its refrangibility, the lungs and the blood to the air, the air-bladder of fish to water, the eye of the seal to the change of the medium in which it must see, the water-pouch in the stomach of the camel to the drought of the African deserts, the sail of the nautilus to the wind that is to drive its little bark, and so on down to the most special and astonishing outward adaptations.[40] We must abstract however here from all temporal relations, for these can only concern the manifestation of the Idea, not the Idea itself. Accordingly this kind of explanation must also be used retrospectively, and we must not merely admit that every species accommodated itself to the given environment, but also that this environment itself, which preceded it in time, had just as much regard for the being that would some time come into it. For it is one and the same will that objectifies itself in the whole world; it knows no time, for this form of the principle of sufficient reason does not belong to it, nor to its original objectivity, the Ideas, but only to the way in which these are known by the individuals who themselves are transitory, *i.e.*, to the manifestation of the Ideas. Thus, time has no significance for our present examination of the manner in which the objectification of the will distributes itself among the Ideas, and the Ideas whose *manifestations* entered into the course of time earlier, according to the law of causality, to which as phenomena they are subject, have no advantage over those whose manifestation entered later; nay rather, these last are the completest objectifications of the will, to which the earlier manifestations must adapt themselves just as much as they must adapt themselves to the earlier. Thus the course of the planets, the tendency to the ellipse, the rotation of the earth, the division of land and sea, the atmosphere, light, warmth, and all such phenomena, which are in nature what bass is in harmony, adapted themselves in anticipation of the coming

species of living creatures of which they were to become the supporter and sustainer. In the same way the ground adapted itself to the nutrition of plants, plants adapted themselves to the nutrition of animals, animals to that of other animals, and conversely they all adapted themselves to the nutrition of the ground. All the parts of nature correspond to each other, for it is *one* will that appears in them all, but the course of time is quite foreign to its original and only *adequate objectification* (this expression will be explained in the following book), the Ideas. Even now, when the species have only to sustain themselves, no longer to come into existence, we see here and there some such forethought of nature extending to the future, and abstracting as it were from the process of time, a self-adaptation of what is to what is yet to come. The bird builds the nest for the young which it does not yet know; the beaver constructs a dam the object of which is unknown to it; ants, marmots, and bees lay in provision for the winter they have never experienced; the spider and the ant-lion make snares, as if with deliberate cunning, for future unknown prey; insects deposit their eggs where the coming brood finds future nourishment. In the spring-time the female flower of the diœcian valisneria unwinds the spirals of its stalk, by which till now it was held at the bottom of the water, and thus rises to the surface. Just then the male flower, which grows on a short stalk from the bottom, breaks away, and so, at the sacrifice of its life, reaches the surface, where it swims about in search of the female. The latter is fructified, and then draws itself down again to the bottom by contracting its spirals, and there the fruit grows.[41] I must again refer here to the larva of the male stag-beetle, which makes the hole in the wood for its metamorphosis as big again as the female does, in order to have room for its future horns. The instinct of animals in general gives us the best illustration of what remains of teleology in nature. For as instinct is an action, like that which is guided by the conception of an end, and yet is entirely without this; so all construction of nature resembles that which is guided by the conception of an end, and yet is entirely without it. For in the outer as in the inner teleology of nature, what we are obliged to think as means and end is, in every case, *the manifestation of the unity of the one will so thoroughly agreeing with itself*, which has assumed multiplicity in space and time for our manner of knowing.

The reciprocal adaptation and self-accommodation of phenomena that springs from this unity cannot, however, annul the inner contradiction which appears in the universal conflict of nature described above, and

which is essential to the will. That harmony goes only so far as to render possible the duration of the world and the different kinds of existences in it, which without it would long since have perished. Therefore it only extends to the continuance of the species, and the general conditions of life, but not to that of the individual. If, then, by reason of that harmony and accommodation, the *species* in organised nature and the *universal forces* in unorganised nature continue to exist beside each other, and indeed support each other reciprocally, on the other hand, the inner contradiction of the will which objectifies itself in all these ideas shows itself in the ceaseless internecine war of the *individuals* of these species, and in the constant struggle of the *manifestations* of these natural forces with each other, as we pointed out above. The scene and the object of this conflict is matter, which they try to wrest from each other, and also space and time, the combination of which through the form of causality is, in fact, matter, as was explained in the First Book.[42]

§ 29. I here conclude the second principal division of my exposition, in the hope that, so far as is possible in the case of an entirely new thought, which cannot be quite free from traces of the individuality in which it originated, I have succeeded in conveying to the reader the complete certainty that this world in which we live and have our being is in its whole nature through and through *will*, and at the same time through and through *idea*: that this idea, as such, already presupposes a form, object and subject, is therefore relative; and if we ask what remains if we take away this form, and all those forms which are subordinate to it, and which express the principle of sufficient reason, the answer must be that as something *toto genere* different from idea, this can be nothing but *will*, which is thus properly the *thing-in-itself*. Every one finds that he himself is this will, in which the real nature of the world consists, and he also finds that he is the knowing subject, whose idea the whole world is, the world which exists only in relation to his consciousness, as its necessary supporter. Every one is thus himself in a double aspect the whole world, the microcosm; finds both sides whole and complete in himself. And what he thus recognises as his own real being also exhausts the being of the whole world — the macrocosm; thus the world, like man, is through and through *will*, and through and through *idea*, and nothing more than this. So we see the philosophy of Thales, which concerned the macrocosm, unite at this point with that of Socrates, which dealt with the microcosm, for the object of both

is found to be the same. But all the knowledge that has been communicated in the two first books will gain greater completeness, and consequently greater certainty, from the two following books, in which I hope that several questions that have more or less distinctly arisen in the course of our work will also be sufficiently answered.

In the meantime *one* such question may be more particularly considered, for it can only properly arise so long as one has not fully penetrated the meaning of the foregoing exposition, and may so far serve as an illustration of it. It is this: Every will is a will towards something, has an object, an end of its willing; what then is the final end, or towards what is that will striving that is exhibited to us as the being-in-itself of the world? This question rests, like so many others, upon the confusion of the thing-in-itself with the manifestation. The principle of sufficient reason, of which the law of motivation is also a form, extends only to the latter, not to the former. It is only of phenomena, of individual things, that a ground can be given, never of the will itself, nor of the Idea in which it adequately objectifies itself. So then of every particular movement or change of any kind in nature, a cause is to be sought, that is, a condition that of necessity produced it, but never of the natural force itself which is revealed in this and innumerable similar phenomena; and it is therefore simple misunderstanding, arising from want of consideration, to ask for a cause of gravity, electricity, and so on. Only if one had somehow shown that gravity and electricity were not original special forces of nature, but only the manifestations of a more general force already known, would it be allowable to ask for the cause which made this force produce the phenomena of gravity or of electricity here. All this has been explained at length above. In the same way every particular act of will of a knowing individual (which is itself only a manifestation of will as the thing-in-itself) has necessarily a motive without which that act would never have occurred; but just as material causes contain merely the determination that at this time, in this place, and in this matter, a manifestation of this or that natural force must take place, so the motive determines only the act of will of a knowing being, at this time, in this place, and under these circumstances, as a particular act, but by no means determines that that being wills in general or wills in this manner; this is the expression of his intelligible character, which, as will itself, the thing-in-itself, is without ground, for it lies outside the province of the principle of sufficient reason. Therefore every man has permanent aims and motives by which he guides

his conduct, and he can always give an account of his particular actions; but if he were asked why he wills at all, or why in general he wills to exist, he would have no answer, and the question would indeed seem to him meaningless; and this would be just the expression of his consciousness that he himself is nothing but will, whose willing stands by itself and requires more particular determination by motives only in its individual acts at each point of time.

In fact, freedom from all aim, from all limits, belongs to the nature of the will, which is an endless striving. This was already touched on above in the reference to centrifugal force. It also discloses itself in its simplest form in the lowest grade of the objectification of will, in gravitation, which we see constantly exerting itself, though a final goal is obviously impossible for it. For if, according to its will, all existing matter were collected in one mass, yet within this mass gravity, ever striving towards the centre, would still wage war with impenetrability as rigidity or elasticity. The tendency of matter can therefore only be confined, never completed or appeased. But this is precisely the case with all tendencies of all phenomena of will. Every attained end is also the beginning of a new course, and so on *ad infinitum*. The plant raises its manifestation from the seed through the stem and the leaf to the blossom and the fruit, which again is the beginning of a new seed, a new individual, that runs through the old course, and so on through endless time. Such also is the life of the animal; procreation is its highest point, and after attaining to it, the life of the first individual quickly or slowly sinks, while a new life ensures to nature the endurance of the species and repeats the same phenomena. Indeed, the constant renewal of the matter of every organism is also to be regarded as merely the manifestation of this continual pressure and change, and physiologists are now ceasing to hold that it is the necessary reparation of the matter wasted in motion, for the possible wearing out of the machine can by no means be equivalent to the support it is constantly receiving through nourishment. Eternal becoming, endless flux, characterises the revelation of the inner nature of will. Finally, the same thing shows itself in human endeavours and desires, which always delude us by presenting their satisfaction as the final end of will. As soon as we attain to them they no longer appear the same, and therefore they soon grow stale, are forgotten, and though not openly disowned, are yet always thrown aside as vanished illusions. We are fortunate enough if there still remains something to wish for and to strive after, that the game may be kept

up of constant transition from desire to satisfaction, and from satisfaction to a new desire, the rapid course of which is called happiness, and the slow course sorrow, and does not sink into that stagnation that shows itself in fearful ennui that paralyses life, vain yearning without a definite object, deadening languor. According to all this, when the will is enlightened by knowledge, it always knows what it wills now and here, never what it wills in general; every particular act of will has its end, the whole will has none; just as every particular phenomenon of nature is determined by a sufficient cause so far as concerns its appearance in this place at this time, but the force which manifests itself in it has no general cause, for it belongs to the thing-in-itself, to the groundless will. The single example of self-knowledge of the will as a whole is the idea as a whole, the whole world of perception. It is the objectification, the revelation, the mirror of the will. What the will expresses in it will be the subject of our further consideration.[43]

Third Book. The World As Idea.

Second Aspect. The Idea Independent Of The Principle Of Sufficient Reason: The Platonic Idea: The Object Of Art.

Τί τὸ ὄν μὲν ἀεί, γένεσιν δὲ οὐκ ἔχον; καὶ τί τό γιγνόμενον μὲν καὶ ἀπολλύμενον, ὄντως δε οὐδέποτε ὄν. —— ΠΛΑΤΩΝ.

§ 30. In the First Book the world was explained as mere *idea*, object for a subject. In the Second Book we considered it from its other side, and found that in this aspect it is *will*, which proved to be simply that which this world is besides being idea. In accordance with this knowledge we called the world as idea, both as a whole and in its parts, the *objectification of will*, which therefore means the will become object, *i.e.*, idea. Further, we remember that this objectification of will was found to have many definite grades, in which, with gradually increasing distinctness and completeness, the nature of will appears in the idea, that is to say, presents itself as object. In these grades we already recognised the Platonic Ideas, for the grades are just the determined species, or the original unchanging forms and qualities of all natural bodies, both organised and unorganised, and also the general forces which reveal themselves according to natural laws. These Ideas, then, as a whole express themselves in innumerable individuals and particulars, and are related to these as archetypes to their copies. The multiplicity of such individuals is only conceivable through time and space, their appearing and passing away through causality, and in all these forms we recognise merely the different modes of the principle of sufficient reason, which is the ultimate principle of all that is finite, of all individual existence, and the universal form of the idea as it appears in the knowledge of the individual as such. The Platonic Idea, on the other hand, does not come under this principle, and has therefore neither multiplicity nor change. While the individuals in which it expresses itself are innumerable, and unceasingly come into being and pass away, it remains unchanged as one and the same, and the principle of sufficient reason has for it no meaning. As, however, this is the form under which all knowledge of the subject comes, so far as the subject knows as an *individual*, the Ideas lie quite outside the sphere of its knowledge. If, therefore, the Ideas are to become objects of knowledge, this can only happen by transcending the

individuality of the knowing subject. The more exact and detailed explanation of this is what will now occupy our attention.

§ 31. First, however, the following very essential remark. I hope that in the preceding book I have succeeded in producing the conviction that what is called in the Kantian philosophy the *thing-in-itself*, and appears there as so significant, and yet so obscure and paradoxical a doctrine, and especially on account of the manner in which Kant introduced it as an inference from the caused to the cause, was considered a stumbling-stone, and, in fact, the weak side of his philosophy, — that this, I say, if it is reached by the entirely different way by which we have arrived at it, is nothing but the *will* when the sphere of that conception is extended and defined in the way I have shown. I hope, further, that after what has been said there will be no hesitation in recognising the definite grades of the objectification of the will, which is the inner reality of the world, to be what Plato called the *eternal Ideas* or unchangeable forms (ειδῆ); a doctrine which is regarded as the principal, but at the same time the most obscure and paradoxical dogma of his system, and has been the subject of reflection and controversy of ridicule and of reverence to so many and such differently endowed minds in the course of many centuries.

If now the will is for us the *thing-in-itself*, and the Idea is the immediate objectivity of that will at a definite grade, we find that Kant's thing-in-itself, and Plato's Idea, which to him is the only οντως ον, these two great obscure paradoxes of the two greatest philosophers of the West are not indeed identical, but yet very closely related, and only distinguished by a single circumstance. The purport of these two great paradoxes, with all inner harmony and relationship, is yet so very different on account of the remarkable diversity of the individuality of their authors, that they are the best commentary on each other, for they are like two entirely different roads that conduct us to the same goal. This is easily made clear. What Kant says is in substance this:— "Time, space, and causality are not determinations of the thing-in-itself, but belong only to its phenomenal existence, for they are nothing but the forms of our knowledge. Since, however, all multiplicity, and all coming into being and passing away, are only possible through time, space, and causality, it follows that they also belong only to the phenomenon, not to the thing-in-itself. But as our knowledge is conditioned by these forms, the whole of experience is only knowledge of the

phenomenon, not of the thing-in-itself; therefore its laws cannot be made valid for the thing-in-itself. This extends even to our own *ego*, and we know it only as phenomenon, and not according to what it may be in itself." This is the meaning and content of the doctrine of Kant in the important respect we are considering. What Plato says is this:— "The things of this world which our senses perceive have no true being; *they always become, they never are:* they have only a relative being; they all exist merely in and through their relations to each other; their whole being may, therefore, quite as well be called a non-being. They are consequently not objects of a true knowledge (επιστημη), for such a knowledge can only be of what exists for itself, and always in the same way; they, on the contrary, are only the objects of an opinion based on sensation (δοξα μετ᾽ αισθησεως αλογου). So long as we are confined to the perception of these, we are like men who sit in a dark cave, bound so fast that they cannot turn their heads, and who see nothing but the shadows of real things which pass between them and a fire burning behind them, the light of which casts the shadows on the wall opposite them; and even of themselves and of each other they see only the shadows on the wall. Their wisdom would thus consist in predicting the order of the shadows learned from experience. The real archetypes, on the other hand, to which these shadows correspond, the eternal Ideas, the original forms of all things, can alone be said to have true being (οντως ον), because they *always are, but never become nor pass away*. To them belongs *no multiplicity*; for each of them is according to its nature only one, for it is the archetype itself, of which all particular transitory things of the same kind which are named after it are copies or shadows. They have also *no coming into being nor passing away*, for they are truly being, never becoming nor vanishing, like their fleeting shadows. (It is necessarily presupposed, however, in these two negative definitions, that time, space, and causality have no significance or validity for these Ideas, and that they do not exist in them.) Of these only can there be true knowledge, for the object of such knowledge can only be that which always and in every respect (thus in-itself) is; not that which is and again is not, according as we look at it." This is Plato's doctrine. It is clear, and requires no further proof that the inner meaning of both doctrines is entirely the same; that both explain the visible world as a manifestation, which in itself is nothing, and which only has meaning and a borrowed reality through that which expresses itself in it (in the one case the thing-in-itself, in the other the

Idea). To this last, which has true being, all the forms of that phenomenal existence, even the most universal and essential, are, according to both doctrines, entirely foreign. In order to disown these forms Kant has directly expressed them even in abstract terms, and distinctly refused time, space, and causality as mere forms of the phenomenon to the thing-in-itself. Plato, on the other hand, did not attain to the fullest expression, and has only distinctly refused these forms to his Ideas in that he denies of the Ideas what is only possible through these forms, multiplicity of similar things, coming into being and passing away. Though it is perhaps superfluous, I should like to illustrate this remarkable and important agreement by an example. There stands before us, let us suppose, an animal in the full activity of life. Plato would say, "This animal has no true existence, but merely an apparent existence, a constant becoming, a relative existence which may just as well be called non-being as being. Only the Idea which expresses itself in that animal is truly 'being,' or the animal in-itself (αυτο το θηριον), which is dependent upon nothing, but is in and for itself (καθ' ἑαυτο, αει ὡς αυτως); it has not become, it will not end, but always is in the same way (αει ον, και μηδεποτε ουτε γυγνομενον ουτε απολλυμενον). If now we recognise its Idea in this animal, it is all one and of no importance whether we have this animal now before us or its progenitor of a thousand years ago, whether it is here or in a distant land, whether it presents itself in this or that manner, position, or action; whether, lastly, it is this or any other individual of the same species; all this is nothing, and only concerns the phenomenon; the Idea of the animal alone has true being, and is the object of real knowledge." So Plato; Kant would say something of this kind, "This animal is a phenomenon in time, space, and causality, which are collectively the conditions *a priori* of the possibility of experience, lying in our faculty of knowledge, not determinations of the thing-in-itself. Therefore this animal as we perceive it at this definite point of time, in this particular place, as an individual in the connection of experience (*i.e.*, in the chain of causes and effects), which has come into being, and will just as necessarily pass away, is not a thing-in-itself, but a phenomenon which only exists in relation to our knowledge. To know it as what it may be in itself, that is to say, independent of all the determinations which lie in time, space, and causality, would demand another kind of knowledge than that which is possible for us through the senses and the understanding."

In order to bring Kant's mode of expression nearer the Platonic, we might say: Time, space, and causality are that arrangement of our intellect by virtue of which the *one* being of each kind which alone really is, manifests itself to us as a multiplicity of similar beings, constantly appearing and disappearing in endless succession. The apprehension of things by means of and in accordance with this arrangement is *immanent* knowledge; that, on the other hand, which is conscious of the true state of the case, is *transcendental* knowledge. The latter is obtained *in abstracto* through the criticism of pure reason, but in exceptional cases it may also appear intuitively. This last is an addition of my own, which I am endeavouring in this Third Book to explain.

If the doctrine of Kant had ever been properly understood and grasped, and since Kant's time that of Plato, if men had truly and earnestly reflected on the inner meaning and content of the teaching of these two great masters, instead of involving themselves in the technicalities of the one and writing parodies of the style of the other, they could not have failed to discern long ago to what an extent these two great philosophers agree, and that the true meaning, the aim of both systems, is the same. Not only would they have refrained from constantly comparing Plato to Leibnitz, on whom his spirit certainly did not rest, or indeed to a well-known gentleman who is still alive,[44] as if they wanted to mock the manes of the great thinker of the past; but they would have advanced much farther in general, or rather they would not have fallen so disgracefully far behind as they have in the last forty years. They would not have let themselves be led by the nose, to-day by one vain boaster and to-morrow by another, nor would they have opened the nineteenth century, which promised so much in Germany, with the philosophical farces that were performed over the grave of Kant (as the ancients sometimes did at the funeral obsequies of their dead), and which deservedly called forth the derision of other nations, for such things least become the earnest and strait-laced German. But so small is the chosen public of true philosophers, that even students who understand are but scantily brought them by the centuries — Εισι δη ναρθηκοφοροι μεν πολλοι, βακχοι δε γε παυροι (*Thyrsigeri quidem multi, Baachi vero pauci*). Ἡ ατιμια φιλοσοφιᾳ δια ταυτα προσπεπτωκεν, ὁτι ου κατ αξιαν αυτης ἁπτονται; ου γαρ νοθους εδει ἁπτεσθαι, αλλα γνησιους (*Eam ob rem philosophia in infamiam incidit, quad non pro dignitate ipsam attingunt: neque enim a spuriis, sad a legitimis erat attrectanda*). — Plato.

Men followed the words, — such words as "*a priori* ideas," "forms of perception and thought existing in consciousness independently of experience," "fundamental conceptions of the pure understanding," &c., &c., — and asked whether Plato's Ideas, which were also original conceptions, and besides this were supposed to be reminiscences of a perception before life of the truly real things, were in some way the same as Kant's forms of perception and thought, which lie *a priori* in our consciousness. On account of some slight resemblance in the expression of these two entirely different doctrines, the Kantian doctrine of the forms which limit the knowledge of the individual to the phenomenon, and the Platonic doctrine of Ideas, the knowledge of which these very forms expressly deny, these so far diametrically opposed doctrines were carefully compared, and men deliberated and disputed as to whether they were identical, found at last that they were not the same, and concluded that Plato's doctrine of Ideas and Kant's "Critique of Reason" had nothing in common. But enough of this.[45]

§ 32. It follows from our consideration of the subject, that, for us, Idea and thing-in-itself are not entirely one and the same, in spite of the inner agreement between Kant and Plato, and the identity of the aim they had before them, or the conception of the world which roused them and led them to philosophise. The Idea is for us rather the direct, and therefore adequate, objectivity of the thing-in-itself, which is, however, itself the *will* — the will as not yet objectified, not yet become idea. For the thing-in-itself must, even according to Kant, be free from all the forms connected with knowing as such; and it is merely an error on his part (as is shown in the Appendix) that he did not count among these forms, before all others, that of being object for a subject, for it is the first and most universal form of all phenomena, *i.e.*, of all idea; he should therefore have distinctly denied objective existence to his thing-in-itself, which would have saved him from a great inconsistency that was soon discovered. The Platonic Idea, on the other hand, is necessarily object, something known, an idea, and in that respect is different from the thing-in-itself, but in that respect only. It has merely laid aside the subordinate forms of the phenomenon, all of which we include in the principle of sufficient reason, or rather it has not yet assumed them; but it has retained the first and most universal form, that of the idea in general, the form of being object for a subject. It is the forms which are subordinate to this (whose general expression is the principle of sufficient

reason) that multiply the Idea in particular transitory individuals, whose number is a matter of complete indifference to the Idea. The principle of sufficient reason is thus again the form into which the Idea enters when it appears in the knowledge of the subject as individual. The particular thing that manifests itself in accordance with the principle of sufficient reason is thus only an indirect objectification of the thing-in-itself (which is the will), for between it and the thing-in-itself stands the Idea as the only direct objectivity of the will, because it has assumed none of the special forms of knowledge as such, except that of the idea in general, *i.e.*, the form of being object for a subject. Therefore it alone is the most *adequate objectivity* of the will or thing-in-itself which is possible; indeed it is the whole thing-in-itself, only under the form of the idea; and here lies the ground of the great agreement between Plato and Kant, although, in strict accuracy, that of which they speak is not the same. But the particular things are no really adequate objectivity of the will, for in them it is obscured by those forms whose general expression is the principle of sufficient reason, but which are conditions of the knowledge which belongs to the individual as such. If it is allowable to draw conclusions from an impossible presupposition, we would, in fact, no longer know particular things, nor events, nor change, nor multiplicity, but would comprehend only Ideas, — only the grades of the objectification of that one will, of the thing-in-itself, in pure unclouded knowledge. Consequently our world would be a *nunc stans*, if it were not that, as knowing subjects, we are also individuals, *i.e.*, our perceptions come to us through the medium of a body, from the affections of which they proceed, and which is itself only concrete willing, objectivity of the will, and thus is an object among objects, and as such comes into the knowing consciousness in the only way in which an object can, through the forms of the principle of sufficient reason, and consequently already presupposes, and therefore brings in, time, and all other forms which that principle expresses. Time is only the broken and piecemeal view which the individual being has of the Ideas, which are outside time, and consequently *eternal*. Therefore Plato says time is the moving picture of eternity: αιωνος εικων κινητη ὁ χρονος.[46]

§ 33. Since now, as individuals, we have no other knowledge than that which is subject to the principle of sufficient reason, and this form of knowledge excludes the Ideas, it is certain that if it is possible for us to raise ourselves from the knowledge of particular things to that of the Ideas, this

can only happen by an alteration taking place in the subject which is analogous and corresponds to the great change of the whole nature of the object, and by virtue of which the subject, so far as it knows an Idea, is no more individual.

It will be remembered from the preceding book that knowledge in general belongs to the objectification of will at its higher grades, and sensibility, nerves, and brain, just like the other parts of the organised being, are the expression of the will at this stage of its objectivity, and therefore the idea which appears through them is also in the same way bound to the service of will as a means (μηχανη) for the attainment of its now complicated (πολυτελεστερα) aims for sustaining a being of manifold requirements. Thus originally and according to its nature, knowledge is completely subject to the will, and, like the immediate object, which, by means of the application of the law of causality, is its starting-point, all knowledge which proceeds in accordance with the principle of sufficient reason remains in a closer or more distant relation to the will. For the individual finds his body as an object among objects, to all of which it is related and connected according to the principle of sufficient reason. Thus all investigations of these relations and connections lead back to his body, and consequently to his will. Since it is the principle of sufficient reason which places the objects in this relation to the body, and, through it, to the will, the one endeavour of the knowledge which is subject to this principle will be to find out the relations in which objects are placed to each other through this principle, and thus to trace their innumerable connections in space, time, and causality. For only through these is the object *interesting* to the individual, *i.e.*, related to the will. Therefore the knowledge which is subject to the will knows nothing further of objects than their relations, knows the objects only so far as they exist at this time, in this place, under these circumstances, from these causes, and with these effects — in a word, as particular things; and if all these relations were to be taken away, the objects would also have disappeared for it, because it knew nothing more about them. We must not disguise the fact that what the sciences consider in things is also in reality nothing more than this; their relations, the connections of time and space, the causes of natural changes, the resemblance of forms, the motives of actions, — thus merely relations. What distinguishes science from ordinary knowledge is merely its systematic form, the facilitating of knowledge by the comprehension of all

particulars in the universal, by means of the subordination of concepts, and the completeness of knowledge which is thereby attained. All relation has itself only a relative existence; for example, all being in time is also non-being; for time is only that by means of which opposite determinations can belong to the same thing; therefore every phenomenon which is in time again is not, for what separates its beginning from its end is only time, which is essentially a fleeting, inconstant, and relative thing, here called duration. But time is the most universal form of all objects of the knowledge which is subject to the will, and the prototype of its other forms.

Knowledge now, as a rule, remains always subordinate to the service of the will, as indeed it originated for this service, and grew, so to speak, to the will, as the head to the body. In the case of the brutes this subjection of knowledge to the will can never be abolished. In the case of men it can be abolished only in exceptional cases, which we shall presently consider more closely. This distinction between man and brute is outwardly expressed by the difference of the relation of the head to the body. In the case of the lower brutes both are deformed: in all brutes the head is directed towards the earth, where the objects of its will lie; even in the higher species the head and the body are still far more one than in the case of man, whose head seems freely set upon his body, as if only carried by and not serving it. This human excellence is exhibited in the highest degree by the Apollo of Belvedere; the head of the god of the Muses, with eyes fixed on the far distance, stands so freely on his shoulders that it seems wholly delivered from the body, and no more subject to its cares.

§ 34. The transition which we have referred to as possible, but yet to be regarded as only exceptional, from the common knowledge of particular things to the knowledge of the Idea, takes place suddenly; for knowledge breaks free from the service of the will, by the subject ceasing to be merely individual, and thus becoming the pure will-less subject of knowledge, which no longer traces relations in accordance with the principle of sufficient reason, but rests in fixed contemplation of the object presented to it, out of its connection with all others, and rises into it.

A full explanation is necessary to make this clear, and the reader must suspend his surprise for a while, till he has grasped the whole thought expressed in this work, and then it will vanish of itself.

If, raised by the power of the mind, a man relinquishes the common way of looking at things, gives up tracing, under the guidance of the forms of the principle of sufficient reason, their relations to each other, the final goal of which is always a relation to his own will; if he thus ceases to consider the where, the when, the why, and the whither of things, and looks simply and solely at the *what*; if, further, he does not allow abstract thought, the concepts of the reason, to take possession of his consciousness, but, instead of all this, gives the whole power of his mind to perception, sinks himself entirely in this, and lets his whole consciousness be filled with the quiet contemplation of the natural object actually present, whether a landscape, a tree, a mountain, a building, or whatever it may be; inasmuch as he *loses* himself in this object (to use a pregnant German idiom), *i.e.*, forgets even his individuality, his will, and only continues to exist as the pure subject, the clear mirror of the object, so that it is as if the object alone were there, without any one to perceive it, and he can no longer separate the perceiver from the perception, but both have become one, because the whole consciousness is filled and occupied with one single sensuous picture; if thus the object has to such an extent passed out of all relation to something outside it, and the subject out of all relation to the will, then that which is so known is no longer the particular thing as such; but it is the *Idea*, the eternal form, the immediate objectivity of the will at this grade; and, therefore, he who is sunk in this perception is no longer individual, for in such perception the individual has lost himself; but he is *pure*, will-less, painless, timeless *subject of knowledge*. This, which in itself is so remarkable (which I well know confirms the saying that originated with Thomas Paine, *Du sublime au ridicule il n'y a qu'un pas*), will by degrees become clearer and less surprising from what follows. It was this that was running in Spinoza's mind when he wrote: *Meus æterna est, quatenus res sub æternitatis specie concipit* (Eth. V. pr. 31, Schol.)[47] In such contemplation the particular thing becomes at once the *Idea* of its species, and the perceiving individual becomes *pure subject of knowledge*. The individual, as such, knows only particular things; the pure subject of knowledge knows only Ideas. For the individual is the subject of knowledge in its relation to a definite particular manifestation of will, and in subjection to this. This particular manifestation of will is, as such, subordinated to the principle of sufficient reason in all its forms; therefore, all knowledge which relates itself to it also follows the principle of sufficient reason, and no other kind of knowledge is fitted to be

of use to the will but this, which always consists merely of relations to the object. The knowing individual as such, and the particular things known by him, are always in some place, at some time, and are links in the chain of causes and effects. The pure subject of knowledge and his correlative, the Idea, have passed out of all these forms of the principle of sufficient reason: time, place, the individual that knows, and the individual that is known, have for them no meaning. When an individual knower has raised himself in the manner described to be pure subject of knowledge, and at the same time has raised the observed object to the Platonic Idea, the *world as idea* appears complete and pure, and the full objectification of the will takes place, for the Platonic Idea alone is its *adequate objectivity*. The Idea includes object and subject in like manner in itself, for they are its one form; but in it they are absolutely of equal importance; for as the object is here, as elsewhere, simply the idea of the subject, the subject, which passes entirely into the perceived object has thus become this object itself, for the whole consciousness is nothing but its perfectly distinct picture. Now this consciousness constitutes the whole *world as idea*, for one imagines the whole of the Platonic Ideas, or grades of the objectivity of will, in their series passing through it. The particular things of all time and space are nothing but Ideas multiplied through the principle of sufficient reason (the form of the knowledge of the individual as such), and thus obscured as regards their pure objectivity. When the Platonic Idea appears, in it subject and object are no longer to be distinguished, for the Platonic Idea, the adequate objectivity of will, the true world as idea, arises only when the subject and object reciprocally fill and penetrate each other completely; and in the same way the knowing and the known individuals, as things in themselves, are not to be distinguished. For if we look entirely away from the true *world as idea*, there remains nothing but the *world as will*. The will is the "in-itself" of the Platonic Idea, which fully objectifies it; it is also the "in-itself" of the particular thing and of the individual that knows it, which objectify it incompletely. As will, outside the idea and all its forms, it is one and the same in the object contemplated and in the individual, who soars aloft in this contemplation, and becomes conscious of himself as pure subject. These two are, therefore, in themselves not different, for in themselves they are will, which here knows itself; and multiplicity and difference exist only as the way in which this knowledge comes to the will,

i.e., only in the phenomenon, on account of its form, the principle of sufficient reason.

Now the known thing, without me as the subject of knowledge, is just as little an object, and not mere will, blind effort, as without the object, without the idea, I am a knowing subject and not mere blind will. This will is in itself, *i.e.*, outside the idea, one and the same with mine: only in the world as idea, whose form is always at least that of subject and object, we are separated as the known and the knowing individual. As soon as knowledge, the world as idea, is abolished, there remains nothing but mere will, blind effort. That it should receive objectivity, become idea, supposes at once both subject and object; but that this should be pure, complete, and adequate objectivity of the will, supposes the object as Platonic Idea, free from the forms of the principle of sufficient reason, and the subject as the pure subject of knowledge, free from individuality and subjection to the will.

Whoever now, has, after the manner referred to, become so absorbed and lost in the perception of nature that he only continues to exist as the pure knowing subject, becomes in this way directly conscious that, as such, he is the condition, that is, the supporter, of the world and all objective existence; for this now shows itself as dependent upon his existence. Thus he draws nature into himself, so that he sees it to be merely an accident of his own being. In this sense Byron says —

“Are not the mountains, waves, and skies, a part
Of me and of my soul, as I of them?”

But how shall he who feels this, regard himself as absolutely transitory, in contrast to imperishable nature? Such a man will rather be filled with the consciousness, which the Upanishad of the Veda expresses: *Hæ omnes creaturæ in totum ego sum, et præter me aliud ens non est* (Oupnek’hat, i. 122).[48]

§ 35. In order to gain a deeper insight into the nature of the world, it is absolutely necessary that we should learn to distinguish the will as thing-in-itself from its adequate objectivity, and also the different grades in which this appears more and more distinctly and fully, *i.e.*, the Ideas themselves, from the merely phenomenal existence of these Ideas in the forms of the principle of sufficient reason, the restricted method of knowledge of the individual. We shall then agree with Plato when he attributes actual being only to the Ideas, and allows only an illusive, dream-like existence to things

in space and time, the real world for the individual. Then we shall understand how one and the same Idea reveals itself in so many phenomena, and presents its nature only bit by bit to the individual, one side after another. Then we shall also distinguish the Idea itself from the way in which its manifestation appears in the observation of the individual, and recognise the former as essential and the latter as unessential. Let us consider this with the help of examples taken from the most insignificant things, and also from the greatest. When the clouds move, the figures which they form are not essential, but indifferent to them; but that as elastic vapour they are pressed together, drifted along, spread out, or torn asunder by the force of the wind: this is their nature, the essence of the forces which objectify themselves in them, the Idea; their actual forms are only for the individual observer. To the brook that flows over stones, the eddies, the waves, the foam-flakes which it forms are indifferent and unessential; but that it follows the attraction of gravity, and behaves as inelastic, perfectly mobile, formless, transparent fluid: this is its nature; this, *if known through perception*, is its Idea; these accidental forms are only for us so long as we know as individuals. The ice on the window-pane forms itself into crystals according to the laws of crystallisation, which reveal the essence of the force of nature that appears here, exhibit the Idea; but the trees and flowers which it traces on the pane are unessential, and are only there for us. What appears in the clouds, the brook, and the crystal is the weakest echo of that will which appears more fully in the plant, more fully still in the beast, and most fully in man. But only the essential in all these grades of its objectification constitutes the Idea; on the other hand, its unfolding or development, because broken up in the forms of the principle of sufficient reason into a multiplicity of many-sided phenomena, is unessential to the Idea, lies merely in the kind of knowledge that belongs to the individual and has reality only for this. The same thing necessarily holds good of the unfolding of that Idea which is the completest objectivity of will. Therefore, the history of the human race, the throng of events, the change of times, the multifarious forms of human life in different lands and countries, all this is only the accidental form of the manifestation of the Idea, does not belong to the Idea itself, in which alone lies the adequate objectivity of the will, but only to the phenomenon which appears in the knowledge of the individual, and is just as foreign, unessential, and indifferent to the Idea itself as the

figures which they assume are to the clouds, the form of its eddies and foam-flakes to the brook, or its trees and flowers to the ice.

To him who has thoroughly grasped this, and can distinguish between the will and the Idea, and between the Idea and its manifestation, the events of the world will have significance only so far as they are the letters out of which we may read the Idea of man, but not in and for themselves. He will not believe with the vulgar that time may produce something actually new and significant; that through it, or in it, something absolutely real may attain to existence, or indeed that it itself as a whole has beginning and end, plan and development, and in some way has for its final aim the highest perfection (according to their conception) of the last generation of man, whose life is a brief thirty years. Therefore he will just as little, with Homer, people a whole Olympus with gods to guide the events of time, as, with Ossian, he will take the forms of the clouds for individual beings; for, as we have said, both have just as much meaning as regards the Idea which appears in them. In the manifold forms of human life and in the unceasing change of events, he will regard the Idea only as the abiding and essential, in which the will to live has its fullest objectivity, and which shows its different sides in the capacities, the passions, the errors and the excellences of the human race; in self-interest, hatred, love, fear, boldness, frivolity, stupidity, slyness, wit, genius, and so forth, all of which crowding together and combining in thousands of forms (individuals), continually create the history of the great and the little world, in which it is all the same whether they are set in motion by nuts or by crowns. Finally, he will find that in the world it is the same as in the dramas of Gozzi, in all of which the same persons appear, with like intention, and with a like fate; the motives and incidents are certainly different in each piece, but the spirit of the incidents is the same; the actors in one piece know nothing of the incidents of another, although they performed in it themselves; therefore, after all experience of former pieces, Pantaloon has become no more agile or generous, Tartaglia no more conscientious, Brighella no more courageous, and Columbine no more modest.

Suppose we were allowed for once a clearer glance into the kingdom of the possible, and over the whole chain of causes and effects; if the earth-spirit appeared and showed us in a picture all the greatest men, enlighteners of the world, and heroes, that chance destroyed before they were ripe for their work; then the great events that would have changed the history of the

world and brought in periods of the highest culture and enlightenment, but which the blindest chance, the most insignificant accident, hindered at the outset; lastly, the splendid powers of great men, that would have enriched whole ages of the world, but which, either misled by error or passion, or compelled by necessity, they squandered uselessly on unworthy or unfruitful objects, or even wasted in play. If we saw all this, we would shudder and lament at the thought of the lost treasures of whole periods of the world. But the earth-spirit would smile and say, "The source from which the individuals and their powers proceed is inexhaustible and unending as time and space; for, like these forms of all phenomena, they also are only phenomena, visibility of the will. No finite measure can exhaust that infinite source; therefore an undiminished eternity is always open for the return of any event or work that was nipped in the bud. In this world of phenomena true loss is just as little possible as true gain. The will alone is; it is the thing in-itself, and the source of all these phenomena. Its self-knowledge and its assertion or denial, which is then decided upon, is the only event in-itself."[49]

§ 36. History follows the thread of events; it is pragmatic so far as it deduces them in accordance with the law of motivation, a law that determines the self-manifesting will wherever it is enlightened by knowledge. At the lowest grades of its objectivity, where it still acts without knowledge, natural science, in the form of etiology, treats of the laws of the changes of its phenomena, and, in the form of morphology, of what is permanent in them. This almost endless task is lightened by the aid of concepts, which comprehend what is general in order that we may deduce what is particular from it. Lastly, mathematics treats of the mere forms, time and space, in which the Ideas, broken up into multiplicity, appear for the knowledge of the subject as individual. All these, of which the common name is science, proceed according to the principle of sufficient reason in its different forms, and their theme is always the phenomenon, its laws, connections, and the relations which result from them. But what kind of knowledge is concerned with that which is outside and independent of all relations, that which alone is really essential to the world, the true content of its phenomena, that which is subject to no change, and therefore is known with equal truth for all time, in a word, the *Ideas*, which are the direct and adequate objectivity of the thing in-itself, the will? We answer, *Art*, the work of genius. It repeats or reproduces the eternal Ideas grasped through pure contemplation, the essential and abiding in all the phenomena

of the world; and according to what the material is in which it reproduces, it is sculpture or painting, poetry or music. Its one source is the knowledge of Ideas; its one aim the communication of this knowledge. While science, following the unresting and inconstant stream of the fourfold forms of reason and consequent, with each end attained sees further, and can never reach a final goal nor attain full satisfaction, any more than by running we can reach the place where the clouds touch the horizon; art, on the contrary, is everywhere at its goal. For it plucks the object of its contemplation out of the stream of the world's course, and has it isolated before it. And this particular thing, which in that stream was a small perishing part, becomes to art the representative of the whole, an equivalent of the endless multitude in space and time. It therefore pauses at this particular thing; the course of time stops; the relations vanish for it; only the essential, the Idea, is its object. We may, therefore, accurately define it as the *way of viewing things independent of the principle of sufficient reason*, in opposition to the way of viewing them which proceeds in accordance with that principle, and which is the method of experience and of science. This last method of considering things may be compared to a line infinitely extended in a horizontal direction, and the former to a vertical line which cuts it at any point. The method of viewing things which proceeds in accordance with the principle of sufficient reason is the rational method, and it alone is valid and of use in practical life and in science. The method which looks away from the content of this principle is the method of genius, which is only valid and of use in art. The first is the method of Aristotle; the second is, on the whole, that of Plato. The first is like the mighty storm, that rushes along without beginning and without aim, bending, agitating, and carrying away everything before it; the second is like the silent sunbeam, that pierces through the storm quite unaffected by it. The first is like the innumerable showering drops of the waterfall, which, constantly changing, never rest for an instant; the second is like the rainbow, quietly resting on this raging torrent. Only through the pure contemplation described above, which ends entirely in the object, can Ideas be comprehended; and the nature of *genius* consists in pre-eminent capacity for such contemplation. Now, as this requires that a man should entirely forget himself and the relations in which he stands, *genius* is simply the completest *objectivity*, *i.e.*, the objective tendency of the mind, as opposed to the subjective, which is directed to one's own self — in other words, to the will. Thus genius is the faculty of

continuing in the state of pure perception, of losing oneself in perception, and of enlisting in this service the knowledge which originally existed only for the service of the will; that is to say, genius is the power of leaving one's own interests, wishes, and aims entirely out of sight, thus of entirely renouncing one's own personality for a time, so as to remain *pure knowing subject*, clear vision of the world; and this not merely at moments, but for a sufficient length of time, and with sufficient consciousness, to enable one to reproduce by deliberate art what has thus been apprehended, and "to fix in lasting thoughts the wavering images that float before the mind." It is as if, when genius appears in an individual, a far larger measure of the power of knowledge falls to his lot than is necessary for the service of an individual will; and this superfluity of knowledge, being free, now becomes subject purified from will, a clear mirror of the inner nature of the world. This explains the activity, amounting even to disquietude, of men of genius, for the present can seldom satisfy them, because it does not fill their consciousness. This gives them that restless aspiration, that unceasing desire for new things, and for the contemplation of lofty things, and also that longing that is hardly ever satisfied, for men of similar nature and of like stature, to whom they might communicate themselves; whilst the common mortal, entirely filled and satisfied by the common present, ends in it, and finding everywhere his like, enjoys that peculiar satisfaction in daily life that is denied to genius.

Imagination has rightly been recognised as an essential element of genius; it has sometimes even been regarded as identical with it; but this is a mistake. As the objects of genius are the eternal Ideas, the permanent, essential forms of the world and all its phenomena, and as the knowledge of the Idea is necessarily knowledge through perception, is not abstract, the knowledge of the genius would be limited to the Ideas of the objects actually present to his person, and dependent upon the chain of circumstances that brought these objects to him, if his imagination did not extend his horizon far beyond the limits of his actual personal existence, and thus enable him to construct the whole out of the little that comes into his own actual apperception, and so to let almost all possible scenes of life pass before him in his own consciousness. Further, the actual objects are almost always very imperfect copies of the Ideas expressed in them; therefore the man of genius requires imagination in order to see in things, not that which Nature has actually made, but that which she endeavoured to

make, yet could not because of that conflict of her forms among themselves which we referred to in the last book. We shall return to this farther on in treating of sculpture. The imagination then extends the intellectual horizon of the man of genius beyond the objects which actually present themselves to him, both as regards quality and quantity. Therefore extraordinary strength of imagination accompanies, and is indeed a necessary condition of genius. But the converse does not hold, for strength of imagination does not indicate genius; on the contrary, men who have no touch of genius may have much imagination. For as it is possible to consider a real object in two opposite ways, purely objectively, the way of genius grasping its Idea, or in the common way, merely in the relations in which it stands to other objects and to one's own will, in accordance with the principle of sufficient reason, it is also possible to perceive an imaginary object in both of these ways. Regarded in the first way, it is a means to the knowledge of the Idea, the communication of which is the work of art; in the second case, the imaginary object is used to build castles in the air congenial to egotism and the individual humour, and which for the moment delude and gratify; thus only the relations of the phantasies so linked together are known. The man who indulges in such an amusement is a dreamer; he will easily mingle those fancies that delight his solitude with reality, and so unfit himself for real life: perhaps he will write them down, and then we shall have the ordinary novel of every description, which entertains those who are like him and the public at large, for the readers imagine themselves in the place of the hero, and then find the story very agreeable.

The common mortal, that manufacture of Nature which she produces by the thousand every day, is, as we have said, not capable, at least not continuously so, of observation that in every sense is wholly disinterested, as sensuous contemplation, strictly so called, is. He can turn his attention to things only so far as they have some relation to his will, however indirect it may be. Since in this respect, which never demands anything but the knowledge of relations, the abstract conception of the thing is sufficient, and for the most part even better adapted for use; the ordinary man does not linger long over the mere perception, does not fix his attention long on one object, but in all that is presented to him hastily seeks merely the concept under which it is to be brought, as the lazy man seeks a chair, and then it interests him no further. This is why he is so soon done with everything, with works of art, objects of natural beauty, and indeed everywhere with the

truly significant contemplation of all the scenes of life. He does not linger; only seeks to know his own way in life, together with all that might at any time become his way. Thus he makes topographical notes in the widest sense; over the consideration of life itself as such he wastes no time. The man of genius, on the other hand, whose excessive power of knowledge frees it at times from the service of will, dwells on the consideration of life itself, strives to comprehend the Idea of each thing, not its relations to other things; and in doing this he often forgets to consider his own path in life, and therefore for the most part pursues it awkwardly enough. While to the ordinary man his faculty of knowledge is a lamp to lighten his path, to the man of genius it is the sun which reveals the world. This great diversity in their way of looking at life soon becomes visible in the outward appearance both of the man of genius and of the ordinary mortal. The man in whom genius lives and works is easily distinguished by his glance, which is both keen and steady, and bears the stamp of perception, of contemplation. This is easily seen from the likenesses of the few men of genius whom Nature has produced here and there among countless millions. On the other hand, in the case of an ordinary man, the true object of his contemplation, what he is prying into, can be easily seen from his glance, if indeed it is not quite stupid and vacant, as is generally the case. Therefore the expression of genius in a face consists in this, that in it a decided predominance of knowledge over will is visible, and consequently there also shows itself in it a knowledge that is entirely devoid of relation to will, *i.e.*, *pure knowing*. On the contrary, in ordinary countenances there is a predominant expression of will; and we see that knowledge only comes into activity under the impulse of will, and thus is directed merely by motives.

Since the knowledge that pertains to genius, or the knowledge of Ideas, is that knowledge which does not follow the principle of sufficient reason, so, on the other hand, the knowledge which does follow that principle is that which gives us prudence and rationality in life, and which creates the sciences. Thus men of genius are affected with the deficiencies entailed in the neglect of this latter kind of knowledge. Yet what I say in this regard is subject to the limitation that it only concerns them in so far as and while they are actually engaged in that kind of knowledge which is peculiar to genius; and this is by no means at every moment of their lives, for the great though spontaneous exertion which is demanded for the comprehension of Ideas free from will must necessarily relax, and there are long intervals

during which men of genius are placed in very much the same position as ordinary mortals, both as regards advantages and deficiencies. On this account the action of genius has always been regarded as an inspiration, as indeed the name indicates, as the action of a superhuman being distinct from the individual himself, and which takes possession of him only periodically. The disinclination of men of genius to direct their attention to the content of the principle of sufficient reason will first show itself, with regard to the ground of being, as dislike of mathematics; for its procedure is based upon the most universal forms of the phenomenon space and time, which are themselves merely modes of the principle of sufficient reason, and is consequently precisely the opposite of that method of thought which seeks merely the content of the phenomenon, the Idea which expresses itself in it apart from all relations. The logical method of mathematics is also antagonistic to genius, for it does not satisfy but obstructs true insight, and presents merely a chain of conclusions in accordance with the principle of the ground of knowing. The mental faculty upon which it makes the greatest claim is memory, for it is necessary to recollect all the earlier propositions which are referred to. Experience has also proved that men of great artistic genius have no faculty for mathematics; no man was ever very distinguished for both. Alfieri relates that he was never able to understand the fourth proposition of Euclid. Goethe was constantly reproached with his want of mathematical knowledge by the ignorant opponents of his theory of colours. Here certainly, where it was not a question of calculation and measurement upon hypothetical data, but of direct knowledge by the understanding of causes and effects, this reproach was so utterly absurd and inappropriate, that by making it they have exposed their entire want of judgment, just as much as by the rest of their ridiculous arguments. The fact that up to the present day, nearly half a century after the appearance of Goethe's theory of colours, even in Germany the Newtonian fallacies still have undisturbed possession of the professorial chair, and men continue to speak quite seriously of the seven homogeneous rays of light and their different refrangibility, will some day be numbered among the great intellectual peculiarities of men generally, and especially of Germans. From the same cause as we have referred to above, may be explained the equally well-known fact that, conversely, admirable mathematicians have very little susceptibility for works of fine art. This is very naïvely expressed in the well-known anecdote of the French mathematician, who, after having read

Racine's "Iphigenia," shrugged his shoulders and asked, "*Qu'est ce que cela prouve?*" Further, as quick comprehension of relations in accordance with the laws of causality and motivation is what specially constitutes prudence or sagacity, a prudent man, so far as and while he is so, will not be a genius, and a man of genius, so far as and while he is so, will not be a prudent man. Lastly, perceptive knowledge generally, in the province of which the Idea always lies, is directly opposed to rational or abstract knowledge, which is guided by the principle of the ground of knowing. It is also well known that we seldom find great genius united with pre-eminent reasonableness; on the contrary, persons of genius are often subject to violent emotions and irrational passions. But the ground of this is not weakness of reason, but partly unwonted energy of that whole phenomenon of will — the man of genius — which expresses itself through the violence of all his acts of will, and partly preponderance of the knowledge of perception through the senses and understanding over abstract knowledge, producing a decided tendency to the perceptible, the exceedingly lively impressions of which so far outshine colourless concepts, that they take their place in the guidance of action, which consequently becomes irrational. Accordingly the impression of the present moment is very strong with such persons, and carries them away into unconsidered action, violent emotions and passions. Moreover, since, in general, the knowledge of persons of genius has to some extent freed itself from the service of will, they will not in conversation think so much of the person they are addressing as of the thing they are speaking about, which is vividly present to them; and therefore they are likely to judge or narrate things too objectively for their own interests; they will not pass over in silence what would more prudently be concealed, and so forth. Finally, they are given to soliloquising, and in general may exhibit certain weaknesses which are actually akin to madness. It has often been remarked that there is a side at which genius and madness touch, and even pass over into each other, and indeed poetical inspiration has been called a kind of madness: *amabilis insania*, Horace calls it (Od. iii. 4), and Wieland in the introduction to "Oberon" speaks of it as "amiable madness." Even Aristotle, as quoted by Seneca (De Tranq. Animi, 15, 16), is reported to have said: *Nullum magnum ingenium sine mixtura dementiæ fuit*. Plato expresses it in the figure of the dark cave, referred to above (De Rep. 7), when he says: "Those who, outside the cave, have seen the true sunlight and the things

that have true being (Ideas), cannot afterwards see properly down in the cave, because their eyes are not accustomed to the darkness; they cannot distinguish the shadows, and are jeered at for their mistakes by those who have never left the cave and its shadows.” In the “Phædrus” also (p. 317), he distinctly says that there can be no true poet without a certain madness; in fact, (p. 327), that every one appears mad who recognises the eternal Ideas in fleeting things. Cicero also quotes: *Negat enim sine furore, Democritus, quemquam poetam magnum esse posse; quod idem dicit Plato* (De Divin., i. 37). And, lastly, Pope says —

“Great wits to madness sure are near allied,
And thin partitions do their bounds divide.”

Especially instructive in this respect is Goethe’s “Torquato Tasso,” in which he shows us not only the suffering, the martyrdom of genius as such, but also how it constantly passes into madness. Finally, the fact of the direct connection of genius and madness is established by the biographies of great men of genius, such as Rousseau, Byron, and Alfieri, and by anecdotes from the lives of others. On the other hand, I must mention that, by a diligent search in lunatic asylums, I have found individual cases of patients who were unquestionably endowed with great talents, and whose genius distinctly appeared through their madness, which, however, had completely gained the upper hand. Now this cannot be ascribed to chance, for on the one hand the number of mad persons is relatively very small, and on the other hand a person of genius is a phenomenon which is rare beyond all ordinary estimation, and only appears in nature as the greatest exception. It will be sufficient to convince us of this if we compare the number of really great men of genius that the whole of civilised Europe has produced, both in ancient and modern times, with the two hundred and fifty millions who are always living in Europe, and who change entirely every thirty years. In estimating the number of men of outstanding genius, we must of course only count those who have produced works which have retained through all time an enduring value for mankind. I shall not refrain from mentioning, that I have known some persons of decided, though not remarkable, mental superiority, who also showed a slight trace of insanity. It might seem from this that every advance of intellect beyond the ordinary measure, as an abnormal development, disposes to madness. In the meantime, however, I will explain as briefly as possible my view of the purely intellectual ground of the relation between genius and madness, for this will certainly assist the

explanation of the real nature of genius, that is to say, of that mental endowment which alone can produce genuine works of art. But this necessitates a brief explanation of madness itself.[50]

A clear and complete insight into the nature of madness, a correct and distinct conception of what constitutes the difference between the sane and the insane, has, as far as I know, not as yet been found. Neither reason nor understanding can be denied to madmen, for they talk and understand, and often draw very accurate conclusions; they also, as a rule, perceive what is present quite correctly, and apprehend the connection between cause and effect. Visions, like the phantasies of delirium, are no ordinary symptom of madness: delirium falsifies perception, madness the thoughts. For the most part, madmen do not err in the knowledge of what is immediately *present*; their raving always relates to what is *absent* and *past*, and only through these to their connection with what is present. Therefore it seems to me that their malady specially concerns the memory; not indeed that memory fails them entirely, for many of them know a great deal by heart, and sometimes recognise persons whom they have not seen for a long time; but rather that the thread of memory is broken, the continuity of its connection destroyed, and no uniformly connected recollection of the past is possible. Particular scenes of the past are known correctly, just like the particular present; but there are gaps in their recollection which they fill up with fictions, and these are either always the same, in which case they become fixed ideas, and the madness that results is called monomania or melancholy; or they are always different, momentary fancies, and then it is called folly, *fatuitas*. This is why it is so difficult to find out their former life from lunatics when they enter an asylum. The true and the false are always mixed up in their memory. Although the immediate present is correctly known, it becomes falsified through its fictitious connection with an imaginary past; they therefore regard themselves and others as identical with persons who exist only in their imaginary past; they do not recognise some of their acquaintances at all, and thus while they perceive correctly what is actually present, they have only false conceptions of its relations to what is absent. If the madness reaches a high degree, there is complete absence of memory, so that the madman is quite incapable of any reference to what is absent or past, and is only determined by the caprice of the moment in connection with the fictions which, in his mind, fill the past. In such a case, we are never for a moment safe from violence or murder, unless we constantly

make the madman aware of the presence of superior force. The knowledge of the madman has this in common with that of the brute, both are confined to the present. What distinguishes them is that the brute has really no idea of the past as such, though the past acts upon it through the medium of custom, so that, for example, the dog recognises its former master even after years, that is to say, it receives the wonted impression at the sight of him; but of the time that has passed since it saw him it has no recollection. The madman, on the other hand, always carries about in his reason an abstract past, but it is a false past, which exists only for him, and that either constantly, or only for the moment. The influence of this false past prevents the use of the true knowledge of the present which the brute is able to make. The fact that violent mental suffering or unexpected and terrible calamities should often produce madness, I explain in the following manner. All such suffering is as an actual event confined to the present. It is thus merely transitory, and is consequently never excessively heavy; it only becomes unendurably great when it is lasting pain; but as such it exists only in thought, and therefore lies in the *memory*. If now such a sorrow, such painful knowledge or reflection, is so bitter that it becomes altogether unbearable, and the individual is prostrated under it, then, terrified Nature seizes upon *madness* as the last resource of life; the mind so fearfully tortured at once destroys the thread of its memory, fills up the gaps with fictions, and thus seeks refuge in madness from the mental suffering that exceeds its strength, just as we cut off a mortified limb and replace it with a wooden one. The distracted Ajax, King Lear, and Ophelia may be taken as examples; for the creations of true genius, to which alone we can refer here, as universally known, are equal in truth to real persons; besides, in this case, frequent actual experience shows the same thing. A faint analogy of this kind of transition from pain to madness is to be found in the way in which all of us often seek, as it were mechanically, to drive away a painful thought that suddenly occurs to us by some loud exclamation or quick movement — to turn ourselves from it, to distract our minds by force.

We see, from what has been said, that the madman has a true knowledge of what is actually present, and also of certain particulars of the past, but that he mistakes the connection, the relations, and therefore falls into error and talks nonsense. Now this is exactly the point at which he comes into contact with the man of genius; for he also leaves out of sight the knowledge of the connection of things, since he neglects that knowledge of

relations which conforms to the principle of sufficient reason, in order to see in things only their Ideas, and to seek to comprehend their true nature, which manifests itself to perception, and in regard to which *one thing* represents its whole species, in which way, as Goethe says, one case is valid for a thousand. The particular object of his contemplation, or the present which is perceived by him with extraordinary vividness, appear in so strong a light that the other links of the chain to which they belong are at once thrown into the shade, and this gives rise to phenomena which have long been recognised as resembling those of madness. That which in particular given things exists only incompletely and weakened by modifications, is raised by the man of genius, through his way of contemplating it, to the Idea of the thing, to completeness: he therefore sees everywhere extremes, and therefore his own action tends to extremes; he cannot hit the mean, he lacks soberness, and the result is what we have said. He knows the Ideas completely but not the individuals. Therefore it has been said that a poet may know mankind deeply and thoroughly, and may yet have a very imperfect knowledge of men. He is easily deceived, and is a tool in the hands of the crafty.

§ 37. Genius, then, consists, according to our explanation, in the capacity for knowing, independently of the principle of sufficient reason, not individual things, which have their existence only in their relations, but the Ideas of such things, and of being oneself the correlative of the Idea, and thus no longer an individual, but the pure subject of knowledge. Yet this faculty must exist in all men in a smaller and different degree; for if not, they would be just as incapable of enjoying works of art as of producing them; they would have no susceptibility for the beautiful or the sublime; indeed, these words could have no meaning for them. We must therefore assume that there exists in all men this power of knowing the Ideas in things, and consequently of transcending their personality for the moment, unless indeed there are some men who are capable of no æsthetic pleasure at all. The man of genius excels ordinary men only by possessing this kind of knowledge in a far higher degree and more continuously. Thus, while under its influence he retains the presence of mind which is necessary to enable him to repeat in a voluntary and intentional work what he has learned in this manner; and this repetition is the work of art. Through this he communicates to others the Idea he has grasped. This Idea remains unchanged and the same, so that æsthetic pleasure is one and the same

whether it is called forth by a work of art or directly by the contemplation of nature and life. The work of art is only a means of facilitating the knowledge in which this pleasure consists. That the Idea comes to us more easily from the work of art than directly from nature and the real world, arises from the fact that the artist, who knew only the Idea, no longer the actual, has reproduced in his work the pure Idea, has abstracted it from the actual, omitting all disturbing accidents. The artist lets us see the world through his eyes. That he has these eyes, that he knows the inner nature of things apart from all their relations, is the gift of genius, is inborn; but that he is able to lend us this gift, to let us see with his eyes, is acquired, and is the technical side of art. Therefore, after the account which I have given in the preceding pages of the inner nature of æsthetical knowledge in its most general outlines, the following more exact philosophical treatment of the beautiful and the sublime will explain them both, in nature and in art, without separating them further. First of all we shall consider what takes place in a man when he is affected by the beautiful and the sublime; whether he derives this emotion directly from nature, from life, or partakes of it only through the medium of art, does not make any essential, but merely an external, difference.

§ 38. In the æsthetical mode of contemplation we have found *two inseparable constituent parts* — the knowledge of the object, not as individual thing but as Platonic Idea, that is, as the enduring form of this whole species of things; and the self-consciousness of the knowing person, not as individual, but as *pure will-less subject of knowledge*. The condition under which both these constituent parts appear always united was found to be the abandonment of the method of knowing which is bound to the principle of sufficient reason, and which, on the other hand, is the only kind of knowledge that is of value for the service of the will and also for science. Moreover, we shall see that the pleasure which is produced by the contemplation of the beautiful arises from these two constituent parts, sometimes more from the one, sometimes more from the other, according to what the object of the æsthetical contemplation may be.

All *willing* arises from want, therefore from deficiency, and therefore from suffering. The satisfaction of a wish ends it; yet for one wish that is satisfied there remain at least ten which are denied. Further, the desire lasts long, the demands are infinite; the satisfaction is short and scantily measured out. But even the final satisfaction is itself only apparent; every

satisfied wish at once makes room for a new one; both are illusions; the one is known to be so, the other not yet. No attained object of desire can give lasting satisfaction, but merely a fleeting gratification; it is like the alms thrown to the beggar, that keeps him alive to-day that his misery may be prolonged till the morrow. Therefore, so long as our consciousness is filled by our will, so long as we are given up to the throng of desires with their constant hopes and fears, so long as we are the subject of willing, we can never have lasting happiness nor peace. It is essentially all the same whether we pursue or flee, fear injury or seek enjoyment; the care for the constant demands of the will, in whatever form it may be, continually occupies and sways the consciousness; but without peace no true well-being is possible. The subject of willing is thus constantly stretched on the revolving wheel of Ixion, pours water into the sieve of the Danaids, is the ever-longing Tantalus.

But when some external cause or inward disposition lifts us suddenly out of the endless stream of willing, delivers knowledge from the slavery of the will, the attention is no longer directed to the motives of willing, but comprehends things free from their relation to the will, and thus observes them without personal interest, without subjectivity, purely objectively, gives itself entirely up to them so far as they are ideas, but not in so far as they are motives. Then all at once the peace which we were always seeking, but which always fled from us on the former path of the desires, comes to us of its own accord, and it is well with us. It is the painless state which Epicurus prized as the highest good and as the state of the gods; for we are for the moment set free from the miserable striving of the will; we keep the Sabbath of the penal servitude of willing; the wheel of Ixion stands still.

But this is just the state which I described above as necessary for the knowledge of the Idea, as pure contemplation, as sinking oneself in perception, losing oneself in the object, forgetting all individuality, surrendering that kind of knowledge which follows the principle of sufficient reason, and comprehends only relations; the state by means of which at once and inseparably the perceived particular thing is raised to the Idea of its whole species, and the knowing individual to the pure subject of will-less knowledge, and as such they are both taken out of the stream of time and all other relations. It is then all one whether we see the sun set from the prison or from the palace.

Inward disposition, the predominance of knowing over willing, can produce this state under any circumstances. This is shown by those admirable Dutch artists who directed this purely objective perception to the most insignificant objects, and established a lasting monument of their objectivity and spiritual peace in their pictures of *still life*, which the æsthetic beholder does not look on without emotion; for they present to him the peaceful, still, frame of mind of the artist, free from will, which was needed to contemplate such insignificant things so objectively, to observe them so attentively, and to repeat this perception so intelligently; and as the picture enables the onlooker to participate in this state, his emotion is often increased by the contrast between it and the unquiet frame of mind, disturbed by vehement willing, in which he finds himself. In the same spirit, landscape-painters, and particularly Ruisdael, have often painted very insignificant country scenes, which produce the same effect even more agreeably.

All this is accomplished by the inner power of an artistic nature alone; but that purely objective disposition is facilitated and assisted from without by suitable objects, by the abundance of natural beauty which invites contemplation, and even presses itself upon us. Whenever it discloses itself suddenly to our view, it almost always succeeds in delivering us, though it may be only for a moment, from subjectivity, from the slavery of the will, and in raising us to the state of pure knowing. This is why the man who is tormented by passion, or want, or care, is so suddenly revived, cheered, and restored by a single free glance into nature: the storm of passion, the pressure of desire and fear, and all the miseries of willing are then at once, and in a marvellous manner, calmed and appeased. For at the moment at which, freed from the will, we give ourselves up to pure will-less knowing, we pass into a world from which everything is absent that influenced our will and moved us so violently through it. This freeing of knowledge lifts us as wholly and entirely away from all that, as do sleep and dreams; happiness and unhappiness have disappeared; we are no longer individual; the individual is forgotten; we are only pure subject of knowledge; we are only that *one* eye of the world which looks out from all knowing creatures, but which can become perfectly free from the service of will in man alone. Thus all difference of individuality so entirely disappears, that it is all the same whether the perceiving eye belongs to a mighty king or to a wretched beggar; for neither joy nor complaining can pass that boundary with us. So

near us always lies a sphere in which we escape from all our misery; but who has the strength to continue long in it? As soon as any single relation to our will, to our person, even of these objects of our pure contemplation, comes again into consciousness, the magic is at an end; we fall back into the knowledge which is governed by the principle of sufficient reason; we know no longer the Idea, but the particular thing, the link of a chain to which we also belong, and we are again abandoned to all our woe. Most men remain almost always at this standpoint because they entirely lack objectivity, *i.e.*, genius. Therefore they have no pleasure in being alone with nature; they need company, or at least a book. For their knowledge remains subject to their will; they seek, therefore, in objects, only some relation to their will, and whenever they see anything that has no such relation, there sounds within them, like a ground bass in music, the constant inconsolable cry, "It is of no use to me;" thus in solitude the most beautiful surroundings have for them a desolate, dark, strange, and hostile appearance.

Lastly, it is this blessedness of will-less perception which casts an enchanting glamour over the past and distant, and presents them to us in so fair a light by means of self-deception. For as we think of days long gone by, days in which we lived in a distant place, it is only the objects which our fancy recalls, not the subject of will, which bore about with it then its incurable sorrows just as it bears them now; but they are forgotten, because since then they have often given place to others. Now, objective perception acts with regard to what is remembered just as it would in what is present, if we let it have influence over us, if we surrendered ourselves to it free from will. Hence it arises that, especially when we are more than ordinarily disturbed by some want, the remembrance of past and distant scenes suddenly flits across our minds like a lost paradise. The fancy recalls only what was objective, not what was individually subjective, and we imagine that that objective stood before us then just as pure and undisturbed by any relation to the will as its image stands in our fancy now; while in reality the relation of the objects to our will gave us pain then just as it does now. We can deliver ourselves from all suffering just as well through present objects as through distant ones whenever we raise ourselves to a purely objective contemplation of them, and so are able to bring about the illusion that only the objects are present and not we ourselves. Then, as the pure subject of knowledge, freed from the miserable self, we become entirely one with these objects, and, for the moment, our wants are as foreign to us as they are

to them. The world as idea alone remains, and the world as will has disappeared.

In all these reflections it has been my object to bring out clearly the nature and the scope of the subjective element in æsthetic pleasure; the deliverance of knowledge from the service of the will, the forgetting of self as an individual, and the raising of the consciousness to the pure will-less, timeless, subject of knowledge, independent of all relations. With this subjective side of æsthetic contemplation, there must always appear as its necessary correlative the objective side, the intuitive comprehension of the Platonic Idea. But before we turn to the closer consideration of this, and to the achievements of art in relation to it, it is better that we should pause for a little at the subjective side of æsthetic pleasure, in order to complete our treatment of this by explaining the impression of the *sublime* which depends altogether upon it, and arises from a modification of it. After that we shall complete our investigation of æsthetic pleasure by considering its objective side.

But we must first add the following remarks to what has been said. Light is the pleasantest and most gladdening of things; it has become the symbol of all that is good and salutary. In all religions it symbolises salvation, while darkness symbolises damnation. Ormuzd dwells in the purest light, Ahrimines in eternal night. Dante's Paradise would look very much like Vauxhall in London, for all the blessed spirits appear as points of light and arrange themselves in regular figures. The very absence of light makes us sad; its return cheers us. Colours excite directly a keen delight, which reaches its highest degree when they are transparent. All this depends entirely upon the fact that light is the correlative and condition of the most perfect kind of knowledge of perception, the only knowledge which does not in any way affect the will. For sight, unlike the affections of the other senses, cannot, in itself, directly and through its sensuous effect, make the *sensation* of the special organ agreeable or disagreeable; that is, it has no immediate connection with the will. Such a quality can only belong to the perception which arises in the understanding, and then it lies in the relation of the object to the will. In the case of hearing this is to some extent otherwise; sounds can give pain directly, and they may also be sensuously agreeable, directly and without regard to harmony or melody. Touch, as one with the feeling of the whole body, is still more subordinated to this direct influence upon the will; and yet there is such a thing as a sensation of touch

which is neither painful nor pleasant. But smells are always either agreeable or disagreeable, and tastes still more so. Thus the last two senses are most closely related to the will, and therefore they are always the most ignoble, and have been called by Kant the subjective senses. The pleasure which we experience from light is in fact only the pleasure which arises from the objective possibility of the purest and fullest perceptive knowledge, and as such it may be traced to the fact that pure knowledge, freed and delivered from all will, is in the highest degree pleasant, and of itself constitutes a large part of æsthetic enjoyment. Again, we must refer to this view of light the incredible beauty which we associate with the reflection of objects in water. That lightest, quickest, finest species of the action of bodies upon each other, that to which we owe by far the completest and purest of our perceptions, the action of reflected rays of light, is here brought clearly before our eyes, distinct and perfect, in cause and in effect, and indeed in its entirety, hence the æsthetic delight it gives us, which, in the most important aspect, is entirely based on the subjective ground of æsthetic pleasure, and is delight in pure knowing and its method.

§ 39. All these reflections are intended to bring out the subjective part of æsthetic pleasure; that is to say, that pleasure so far as it consists simply of delight in perceptive knowledge as such, in opposition to will. And as directly connected with this, there naturally follows the explanation of that disposition or frame of mind which has been called the sense of the *sublime*.

We have already remarked above that the transition to the state of pure perception takes place most easily when the objects bend themselves to it, that is, when by their manifold and yet definite and distinct form they easily become representatives of their Ideas, in which beauty, in the objective sense, consists. This quality belongs pre-eminently to natural beauty, which thus affords even to the most insensible at least a fleeting æsthetic satisfaction: indeed it is so remarkable how especially the vegetable world invites æsthetic observation, and, as it were, presses itself upon it, that one might say, that these advances are connected with the fact that these organisms, unlike the bodies of animals, are not themselves immediate objects of knowledge, and therefore require the assistance of a foreign intelligent individual in order to rise out of the world of blind will and enter the world of idea, and that thus they long, as it were, for this entrance, that they may attain at least indirectly what is denied them directly. But I leave this suggestion which I have hazarded, and which

borders perhaps upon extravagance, entirely undecided, for only a very intimate and devoted consideration of nature can raise or justify it.[51] As long as that which raises us from the knowledge of mere relations subject to the will, to æsthetic contemplation, and thereby exalts us to the position of the subject of knowledge free from will, is this fittingness of nature, this significance and distinctness of its forms, on account of which the Ideas individualised in them readily present themselves to us; so long is it merely *beauty* that affects us and the sense of the *beautiful* that is excited. But if these very objects whose significant forms invite us to pure contemplation, have a hostile relation to the human will in general, as it exhibits itself in its objectivity, the human body, if they are opposed to it, so that it is menaced by the irresistible predominance of their power, or sinks into insignificance before their immeasurable greatness; if, nevertheless, the beholder does not direct his attention to this eminently hostile relation to his will, but, although perceiving and recognising it, turns consciously away from it, forcibly detaches himself from his will and its relations, and, giving himself up entirely to knowledge, quietly contemplates those very objects that are so terrible to the will, comprehends only their Idea, which is foreign to all relation, so that he lingers gladly over its contemplation, and is thereby raised above himself, his person, his will, and all will: — in that case he is filled with the sense of the *sublime*, he is in the state of spiritual exaltation, and therefore the object producing such a state is called *sublime*. Thus what distinguishes the sense of the sublime from that of the beautiful is this: in the case of the beautiful, pure knowledge has gained the upper hand without a struggle, for the beauty of the object, *i.e.*, that property which facilitates the knowledge of its Idea, has removed from consciousness without resistance, and therefore imperceptibly, the will and the knowledge of relations which is subject to it, so that what is left is the pure subject of knowledge without even a remembrance of will. On the other hand, in the case of the sublime that state of pure knowledge is only attained by a conscious and forcible breaking away from the relations of the same object to the will, which are recognised as unfavourable, by a free and conscious transcending of the will and the knowledge related to it.

This exaltation must not only be consciously won, but also consciously retained, and it is therefore accompanied by a constant remembrance of will; yet not of a single particular volition, such as fear or desire, but of human volition in general, so far as it is universally expressed in its

objectivity the human body. If a single real act of will were to come into consciousness, through actual personal pressure and danger from the object, then the individual will thus actually influenced would at once gain the upper hand, the peace of contemplation would become impossible, the impression of the sublime would be lost, because it yields to the anxiety, in which the effort of the individual to right itself has sunk every other thought. A few examples will help very much to elucidate this theory of the æsthetic sublime and remove all doubt with regard to it; at the same time they will bring out the different degrees of this sense of the sublime. It is in the main identical with that of the beautiful, with pure will-less knowing, and the knowledge, that necessarily accompanies it of Ideas out of all relation determined by the principle of sufficient reason, and it is distinguished from the sense of the beautiful only by the additional quality that it rises above the known hostile relation of the object contemplated to the will in general. Thus there come to be various degrees of the sublime, and transitions from the beautiful to the sublime, according as this additional quality is strong, bold, urgent, near, or weak, distant, and merely indicated. I think it is more in keeping with the plan of my treatise, first to give examples of these transitions, and of the weaker degrees of the impression of the sublime, although persons whose æsthetical susceptibility in general is not very great, and whose imagination is not very lively, will only understand the examples given later of the higher and more distinct grades of that impression; and they should therefore confine themselves to these, and pass over the examples of the very weak degrees of the sublime that are to be given first.

As man is at once impetuous and blind striving of will (whose pole or focus lies in the genital organs), and eternal, free, serene subject of pure knowing (whose pole is the brain); so, corresponding to this antithesis, the sun is both the source of *light*, the condition of the most perfect kind of knowledge, and therefore of the most delightful of things — and the source of *warmth*, the first condition of life, *i.e.*, of all phenomena of will in its higher grades. Therefore, what warmth is for the will, light is for knowledge. Light is the largest gem in the crown of beauty, and has the most marked influence on the knowledge of every beautiful object. Its presence is an indispensable condition of beauty; its favourable disposition increases the beauty of the most beautiful. Architectural beauty more than any other object is enhanced by favourable light, though even the most

insignificant things become through its influence most beautiful. If, in the dead of winter, when all nature is frozen and stiff, we see the rays of the setting sun reflected by masses of stone, illuminating without warming, and thus favourable only to the purest kind of knowledge, not to the will; the contemplation of the beautiful effect of the light upon these masses lifts us, as does all beauty, into a state of pure knowing. But, in this case, a certain transcending of the interests of the will is needed to enable us to rise into the state of pure knowing, because there is a faint recollection of the lack of warmth from these rays, that is, an absence of the principle of life; there is a slight challenge to persist in pure knowing, and to refrain from all willing, and therefore it is an example of a transition from the sense of the beautiful to that of the sublime. It is the faintest trace of the sublime in the beautiful; and beauty itself is indeed present only in a slight degree. The following is almost as weak an example.

Let us imagine ourselves transported to a very lonely place, with unbroken horizon, under a cloudless sky, trees and plants in the perfectly motionless air, no animals, no men, no running water, the deepest silence. Such surroundings are, as it were, a call to seriousness and contemplation, apart from all will and its cravings; but this is just what imparts to such a scene of desolate stillness a touch of the sublime. For, because it affords no object, either favourable or unfavourable, for the will which is constantly in need of striving and attaining, there only remains the state of pure contemplation, and whoever is incapable of this, is ignominiously abandoned to the vacancy of unoccupied will, and the misery of ennui. So far it is a test of our intellectual worth, of which, generally speaking, the degree of our power of enduring solitude, or our love of it, is a good criterion. The scene we have sketched affords us, then, an example of the sublime in a low degree, for in it, with the state of pure knowing in its peace and all-sufficiency, there is mingled, by way of contrast, the recollection of the dependence and poverty of the will which stands in need of constant action. This is the species of the sublime for which the sight of the boundless prairies of the interior of North America is celebrated.

But let us suppose such a scene, stripped also of vegetation, and showing only naked rocks; then from the entire absence of that organic life which is necessary for existence, the will at once becomes uneasy, the desert assumes a terrible aspect, our mood becomes more tragic; the elevation to the sphere of pure knowing takes place with a more decided tearing of

ourselves away from the interests of the will; and because we persist in continuing in the state of pure knowing, the sense of the sublime distinctly appears.

The following situation may occasion this feeling in a still higher degree: Nature convulsed by a storm; the sky darkened by black threatening thunder-clouds; stupendous, naked, overhanging cliffs, completely shutting out the view; rushing, foaming torrents; absolute desert; the wail of the wind sweeping through the clefts of the rocks. Our dependence, our strife with hostile nature, our will broken in the conflict, now appears visibly before our eyes. Yet, so long as the personal pressure does not gain the upper hand, but we continue in æsthetic contemplation, the pure subject of knowing gazes unshaken and unconcerned through that strife of nature, through that picture of the broken will, and quietly comprehends the Ideas even of those objects which are threatening and terrible to the will. In this contrast lies the sense of the sublime.

But the impression becomes still stronger, if, when we have before our eyes, on a large scale, the battle of the raging elements, in such a scene we are prevented from hearing the sound of our own voice by the noise of a falling stream; or, if we are abroad in the storm of tempestuous seas, where the mountainous waves rise and fall, dash themselves furiously against steep cliffs, and toss their spray high into the air; the storm howls, the sea boils, the lightning flashes from black clouds, and the peals of thunder drown the voice of storm and sea. Then, in the undismayed beholder, the two-fold nature of his consciousness reaches the highest degree of distinctness. He perceives himself, on the one hand, as an individual, as the frail phenomenon of will, which the slightest touch of these forces can utterly destroy, helpless against powerful nature, dependent, the victim of chance, a vanishing nothing in the presence of stupendous might; and, on the other hand, as the eternal, peaceful, knowing subject, the condition of the object, and, therefore, the supporter of this whole world; the terrific strife of nature only his idea; the subject itself free and apart from all desires and necessities, in the quiet comprehension of the Ideas. This is the complete impression of the sublime. Here he obtains a glimpse of a power beyond all comparison superior to the individual, threatening it with annihilation.

The impression of the sublime may be produced in quite another way, by presenting a mere immensity in space and time; its immeasurable greatness

dwindles the individual to nothing. Adhering to Kant's nomenclature and his accurate division, we may call the first kind the dynamical, and the second the mathematical sublime, although we entirely dissent from his explanation of the inner nature of the impression, and can allow no share in it either to moral reflections, or to hypostases from scholastic philosophy.

If we lose ourselves in the contemplation of the infinite greatness of the universe in space and time, meditate on the thousands of years that are past or to come, or if the heavens at night actually bring before our eyes innumerable worlds and so force upon our consciousness the immensity of the universe, we feel ourselves dwindle to nothing; as individuals, as living bodies, as transient phenomena of will, we feel ourselves pass away and vanish into nothing like drops in the ocean. But at once there rises against this ghost of our own nothingness, against such lying impossibility, the immediate consciousness that all these worlds exist only as our idea, only as modifications of the eternal subject of pure knowing, which we find ourselves to be as soon as we forget our individuality, and which is the necessary supporter of all worlds and all times the condition of their possibility. The vastness of the world which disquieted us before, rests now in us; our dependence upon it is annulled by its dependence upon us. All this, however, does not come at once into reflection, but shows itself merely as the felt consciousness that in some sense or other (which philosophy alone can explain) we are one with the world, and therefore not oppressed, but exalted by its immensity. It is the felt consciousness of this that the Upanishads of the Vedas repeatedly express in such a multitude of different ways; very admirably in the saying already quoted: *Hæ omnes creaturæ in totum ego sum, et præter me aliud ens non est* (Oupnek'hat, vol. i. p. 122.) It is the transcending of our own individuality, the sense of the sublime.

We receive this impression of the mathematical-sublime, quite directly, by means of a space which is small indeed as compared with the world, but which has become directly perceptible to us, and affects us with its whole extent in all its three dimensions, so as to make our own body seem almost infinitely small. An empty space can never be thus perceived, and therefore never an open space, but only space that is directly perceptible in all its dimensions by means of the limits which enclose it; thus for example a very high, vast dome, like that of St. Peter's at Rome, or St. Paul's in London. The sense of the sublime here arises through the consciousness of the vanishing nothingness of our own body in the presence of a vastness which,

from another point of view, itself exists only in our idea, and of which we are as knowing subject, the supporter. Thus here as everywhere it arises from the contrast between the insignificance and dependence of ourselves as individuals, as phenomena of will, and the consciousness of ourselves as pure subject of knowing. Even the vault of the starry heaven produces this if it is contemplated without reflection; but just in the same way as the vault of stone, and only by its apparent, not its real extent. Some objects of our perception excite in us the feeling of the sublime because, not only on account of their spatial vastness, but also of their great age, that is, their temporal duration, we feel ourselves dwarfed to insignificance in their presence, and yet revel in the pleasure of contemplating them: of this kind are very high mountains, the Egyptian pyramids, and colossal ruins of great antiquity.

Our explanation of the sublime applies also to the ethical, to what is called the sublime character. Such a character arises from this, that the will is not excited by objects which are well calculated to excite it, but that knowledge retains the upper hand in their presence. A man of sublime character will accordingly consider men in a purely objective way, and not with reference to the relations which they might have to his will; he will, for example, observe their faults, even their hatred and injustice to himself, without being himself excited to hatred; he will behold their happiness without envy; he will recognise their good qualities without desiring any closer relations with them; he will perceive the beauty of women, but he will not desire them. His personal happiness or unhappiness will not greatly affect him, he will rather be as Hamlet describes Horatio: —

"... for thou hast been,
As one, in suffering all, that suffers nothing;
A man that fortune's buffets and rewards
Hast ta'en with equal thanks," &c. (A. 3. Sc. 2.)

For in the course of his own life and its misfortunes, he will consider less his individual lot than that of humanity in general, and will therefore conduct himself in its regard, rather as knowing than as suffering.

§ 40. Opposites throw light upon each other, and therefore the remark may be in place here, that the proper opposite of the sublime is something which would not at the first glance be recognised, as such: *the charming* or *attractive*. By this, however, I understand, that which excites the will by presenting to it directly its fulfilment, its satisfaction. We saw that the

feeling of the sublime arises from the fact, that something entirely unfavourable to the will, becomes the object of pure contemplation, so that such contemplation can only be maintained by persistently turning away from the will, and transcending its interests; this constitutes the sublimity of the character. The charming or attractive, on the contrary, draws the beholder away from the pure contemplation which is demanded by all apprehension of the beautiful, because it necessarily excites this will, by objects which directly appeal to it, and thus he no longer remains pure subject of knowing, but becomes the needy and dependent subject of will. That every beautiful thing which is bright or cheering should be called charming, is the result of a too general concept, which arises from a want of accurate discrimination, and which I must entirely set aside, and indeed condemn. But in the sense of the word which has been given and explained, I find only two species of the charming or attractive in the province of art, and both of them are unworthy of it. The one species, a very low one, is found in Dutch paintings of still life, when they err by representing articles of food, which by their deceptive likeness necessarily excite the appetite for the things they represent, and this is just an excitement of the will, which puts an end to all æsthetic contemplation of the object. Painted fruit is yet admissible, because we may regard it as the further development of the flower, and as a beautiful product of nature in form and colour, without being obliged to think of it as eatable; but unfortunately we often find, represented with deceptive naturalness, prepared and served dishes, oysters, herrings, crabs, bread and butter, beer, wine, and so forth, which is altogether to be condemned. In historical painting and in sculpture the charming consists in naked figures, whose position, drapery, and general treatment are calculated to excite the passions of the beholder, and thus pure æsthetical contemplation is at once annihilated, and the aim of art is defeated. This mistake corresponds exactly to that which we have just censured in the Dutch paintings. The ancients are almost always free from this fault in their representations of beauty and complete nakedness of form, because the artist himself created them in a purely objective spirit, filled with ideal beauty, not in the spirit of subjective, and base sensuality. The charming is thus everywhere to be avoided in art.

There is also a negative species of the charming or exciting which is even more reprehensible than the positive form which has been discussed; this is the disgusting or the loathsome. It arouses the will of the beholder,

just as what is properly speaking charming, and therefore disturbs pure æsthetic contemplation. But it is an active aversion and opposition which is excited by it; it arouses the will by presenting to it objects which it abhors. Therefore it has always been recognised that it is altogether inadmissible in art, where even what is ugly, when it is not disgusting, is allowable in its proper place, as we shall see later.

§ 41. The course of the discussion has made it necessary to insert at this point the treatment of the sublime, though we have only half done with the beautiful, as we have considered its subjective side only. For it was merely a special modification of this subjective side that distinguished the beautiful from the sublime. This difference was found to depend upon whether the state of pure will-less knowing, which is presupposed and demanded by all æsthetic contemplation, was reached without opposition, by the mere disappearance of the will from consciousness, because the object invited and drew us towards it; or whether it was only attained through the free, conscious transcending of the will, to which the object contemplated had an unfavourable and even hostile relation, which would destroy contemplation altogether, if we were to give ourselves up to it. This is the distinction between the beautiful and the sublime. In the object they are not essentially different, for in every case the object of æsthetical contemplation is not the individual thing, but the Idea in it which is striving to reveal itself; that is to say, adequate objectivity of will at a particular grade. Its necessary correlative, independent, like itself of the principle of sufficient reason, is the pure subject of knowing; just as the correlative of the particular thing is the knowing individual, both of which lie within the province of the principle of sufficient reason.

When we say that a thing is *beautiful*, we thereby assert that it is an object of our æsthetic contemplation, and this has a double meaning; on the one hand it means that the sight of the thing makes us *objective*, that is to say, that in contemplating it we are no longer conscious of ourselves as individuals, but as pure will-less subjects of knowledge; and on the other hand it means that we recognise in the object, not the particular thing, but an Idea; and this can only happen, so far as our contemplation of it is not subordinated to the principle of sufficient reason, does not follow the relation of the object to anything outside it (which is always ultimately connected with relations to our own will), but rests in the object itself. For the Idea and the pure subject of knowledge always appear at once in

consciousness as necessary correlatives, and on their appearance all distinction of time vanishes, for they are both entirely foreign to the principle of sufficient reason in all its forms, and lie outside the relations which are imposed by it; they may be compared to the rainbow and the sun, which have no part in the constant movement and succession of the falling drops. Therefore, if, for example, I contemplate a tree æsthetically, *i.e.*, with artistic eyes, and thus recognise, not it, but its Idea, it becomes at once of no consequence whether it is this tree or its predecessor which flourished a thousand years ago, and whether the observer is this individual or any other that lived anywhere and at any time; the particular thing and the knowing individual are abolished with the principle of sufficient reason, and there remains nothing but the Idea and the pure subject of knowing, which together constitute the adequate objectivity of will at this grade. And the Idea dispenses not only with time, but also with space, for the Idea proper is not this special form which appears before me but its expression, its pure significance, its inner being, which discloses itself to me and appeals to me, and which may be quite the same though the spatial relations of its form be very different.

Since, on the one hand, every given thing may be observed in a. purely objective manner and apart from all relations; and since, on the other hand, the will manifests itself in everything at some grade of its objectivity, so that everything is the expression of an Idea; it follows that everything is also *beautiful*. That even the most insignificant things admit of pure objective and will-less contemplation, and thus prove that they are beautiful, is shown by what was said above in this reference about the Dutch pictures of still-life (§ 38). But one thing is more beautiful than another, because it makes this pure objective contemplation easier, it lends itself to it, and, so to speak, even compels it, and then we call it very beautiful. This is the case sometimes because, as an individual thing, it expresses in its purity the Idea of its species by the very distinct, clearly defined, and significant relation of its parts, and also fully reveals that Idea through the completeness of all the possible expressions of its species united in it, so that it makes the transition from the individual thing to the Idea, and therefore also the condition of pure contemplation, very easy for the beholder. Sometimes this possession of special beauty in an object lies in the fact that the Idea itself which appeals to us in it is a high grade of the objectivity of will, and therefore very significant and expressive. Therefore

it is that man is more beautiful than all other objects, and the revelation of his nature is the highest aim of art. Human form and expression are the most important objects of plastic art, and human action the most important object of poetry. Yet each thing has its own peculiar beauty, not only every organism which expresses itself in the unity of an individual being, but also everything unorganised and formless, and even every manufactured article. For all these reveal the Ideas through which the will objectifies itself at its lowest grades, they give, as it were, the deepest resounding bass-notes of nature. Gravity, rigidity, fluidity, light, and so forth, are the Ideas which express themselves in rocks, in buildings, in waters. Landscape-gardening or architecture can do no more than assist them to unfold their qualities distinctly, fully, and variously; they can only give them the opportunity of expressing themselves purely, so that they lend themselves to æsthetic contemplation and make it easier. Inferior buildings or ill-favoured localities, on the contrary, which nature has neglected or art has spoiled, perform this task in a very slight degree or not at all; yet even from them these universal, fundamental Ideas of nature cannot altogether disappear. To the careful observer they present themselves here also, and even bad buildings and the like are capable of being æsthetically considered; the Ideas of the most universal properties of their materials are still recognisable in them, only the artificial form which has been given them does not assist but hinders æsthetic contemplation. Manufactured articles also serve to express Ideas, only it is not the Idea of the manufactured article which speaks in them, but the Idea of the material to which this artificial form has been given. This may be very conveniently expressed in two words, in the language of the schoolmen, thus, — the manufactured article expresses the Idea of its *forma substantialis*, but not that of its *forma accidentalis*; the latter leads to no Idea, but only to a human conception of which it is the result. It is needless to say that by manufactured article no work of plastic art is meant. The schoolmen understand, in fact, by *forma substantialis* that which I call the grade of the objectification of will in a thing. We shall return immediately, when we treat of architecture, to the Idea of the material. Our view, then, cannot be reconciled with that of Plato if he is of opinion that a table or a chair express the Idea of a table or a chair (De Rep., x., pp. 284, 285, et Parmen., p. 79, ed. Bip.), but we say that they express the Ideas which are already expressed in their mere material as such. According to Aristotle (Metap. xi., chap. 3), however, Plato himself

only maintained Ideas of natural objects: ὁ Πλατων εφη, ὁτι ειδη εστιν ὁποσα φυσει (*Plato dixit, quod ideæ eorum sunt, quæ natura sunt*), and in chap. 5 he says that, according to the Platonists, there are no Ideas of house and ring. In any case, Plato's earliest disciples, as Alcinous informs us (*Introductio in Platonicam Philosophiam*, chap. 9), denied that there were any ideas of manufactured articles. He says: Ὁριζονται δε την ιδεαν, παραδειγμα των κατα φυσιν αιωνιον. Ουτε γαρ τοις πλειστοις των απο Πλατωνος αρεσκει, των τεχνικων ειναι ιδεας, οἱον ασπιδος η λυρας, ουτε μην των παρα φυσιν, οἱον πυρετου και χολερας, ουτε των κατα μερος, οἱον Σωκρατους και Πλατωνος, αλλ᾽ ουτε των ευτελων τινος, οἱον ρυπου και καρφους, ουτε των προς τι, οἱον μειζονος και ὑπερεχοντος; ειναι γαρ τας ιδεας νοησεις θεου αιωνιους τε και αυτοτελεις (*Definiunt autem* ideam *exemplar æternum eorum, quæ secundum naturam existunt. Nam plurimis ex iis, qui Platonem secuti sunt, minime placuit, arte factorum ideas esse, ut clypei atque lyræ; neque rursus eorum, quæ prætor naturam, ut febris et choleræ, neque particularium, ceu Socratis et Platonis; neque etiam rerum vilium, veluti sordium et festucæ; neque relationum, ut majoris et excedentis: esse namque ideas intellectiones dei æternas, ac seipsis perfectas*). We may take this opportunity of mentioning another point in which our doctrine of Ideas differs very much from that of Plato. He teaches (De Rep., x., p. 288) that the object which art tries to express, the ideal of painting and poetry, is not the Idea but the particular thing. Our whole exposition hitherto has maintained exactly the opposite, and Plato's opinion is the less likely to lead us astray, inasmuch as it is the source of one of the greatest and best known errors of this great man, his depreciation and rejection of art, and especially poetry; he directly connects his false judgment in reference to this with the passage quoted.

§ 42. I return to the exposition of the æsthetic impression. The knowledge of the beautiful always supposes at once and inseparably the pure knowing subject and the known Idea as object. Yet the source of æsthetic satisfaction will sometimes lie more in the comprehension of the known Idea, sometimes more in the blessedness and spiritual peace of the pure knowing subject freed from all willing, and therefore from all individuality, and the pain that proceeds from it. And, indeed, this predominance of one or the other constituent part of æsthetic feeling will depend upon whether the intuitively grasped Idea is a higher or a lower

grade of the objectivity of will. Thus in æsthetic contemplation (in the real, or through the medium of art) of the beauty of nature in the inorganic and vegetable worlds, or in works of architecture, the pleasure of pure will-less knowing will predominate, because the Ideas which are here apprehended are only low grades of the objectivity of will, and are therefore not manifestations of deep significance and rich content. On the other hand, if animals and man are the objects of æsthetic contemplation or representation, the pleasure will consist rather in the comprehension of these Ideas, which are the most distinct revelation of will; for they exhibit the greatest multiplicity of forms, the greatest richness and deep significance of phenomena, and reveal to us most completely the nature of will, whether in its violence, its terribleness, its satisfaction or its aberration (the latter in tragic situations), or finally in its change and self-surrender, which is the peculiar theme of christian painting; as the Idea of the will enlightened by full knowledge is the object of historical painting in general, and of the drama. We shall now go through the fine arts one by one, and this will give completeness and distinctness to the theory of the beautiful which we have advanced.

§ 43. Matter as such cannot be the expression of an Idea. For, as we found in the first book, it is throughout nothing but causality: its being consists in its casual action. But causality is a form of the principle of sufficient reason; knowledge of the Idea, on the other hand, absolutely excludes the content of that principle. We also found, in the second book, that matter is the common substratum of all particular phenomena of the Ideas, and consequently is the connecting link between the Idea and the phenomenon, or the particular thing. Accordingly for both of these reasons it is impossible that matter can for itself express any Idea. This is confirmed *a posteriori* by the fact that it is impossible to have a perceptible idea of matter as such, but only an abstract conception; in the former, *i.e.*, in perceptible ideas are exhibited only the forms and qualities of which matter is the supporter, and in all of which Ideas reveal themselves. This corresponds also with the fact, that causality (the whole essence of matter) cannot for itself be presented perceptibly, but is merely a definite casual connection. On the other hand, *every phenomenon* of an Idea, because as such it has entered the form of the principle of sufficient reason, or the *principium individuationis*, must exhibit itself in matter, as one of its qualities. So far then matter is, as we have said, the connecting link between

the Idea and the *principium individuationis*, which is the form of knowledge of the individual, or the principle of sufficient reason. Plato is therefore perfectly right in his enumeration, for after the Idea and the phenomenon, which include all other things in the world, he gives matter only, as a third thing which is different from both (Timaus, p. 345). The individual, as a phenomenon of the Idea, is always matter. Every quality of matter is also the phenomenon of an Idea, and as such it may always be an object of æsthetic contemplation, *i.e.*, the Idea expressed in it may always be recognised. This holds good of even the most universal qualities of matter, without which it never appears, and which are the weakest objectivity of will. Such are gravity, cohesion, rigidity, fluidity, sensitiveness to light, and so forth.

If now we consider *architecture* simply as a fine art and apart from its application to useful ends, in which it serves the will and not pure knowledge, and therefore ceases to be art in our sense; we can assign to it no other aim than that of bringing to greater distinctness some of those ideas, which are the lowest grades of the objectivity of will; such as gravity, cohesion, rigidity, hardness, those universal qualities of stone, those first, simplest, most inarticulate manifestations of will; the bass notes of nature; and after these light, which in many respects is their opposite. Even at these low grades of the objectivity of will we see its nature revealing itself in discord; for properly speaking the conflict between gravity and rigidity is the sole æsthetic material of architecture; its problem is to make this conflict appear with perfect distinctness in a multitude of different ways. It solves it by depriving these indestructible forces of the shortest way to their satisfaction, and conducting them to it by a circuitous route, so that the conflict is lengthened and the inexhaustible efforts of both forces become visible in many different ways. The whole mass of the building, if left to its original tendency, would exhibit a mere heap or clump, bound as closely as possible to the earth, to which gravity, the form in which the will appears here, continually presses, while rigidity, also objectivity of will, resists. But this very tendency, this effort, is hindered by architecture from obtaining direct satisfaction, and only allowed to reach it indirectly and by roundabout ways. The roof, for example, can only press the earth through columns, the arch must support itself, and can only satisfy its tendency towards the earth through the medium of the pillars, and so forth. But just by these enforced digressions, just by these restrictions, the forces which reside in the crude

mass of stone unfold themselves in the most distinct and multifarious ways; and the purely æsthetic aim of architecture can go no further than this. Therefore the beauty, at any rate, of a building lies in the obvious adaptation of every part, not to the outward arbitrary end of man (so far the work belongs to practical architecture), but directly to the stability of the whole, to which the position, dimensions, and form of every part must have so necessary a relation that, where it is possible, if any one part were taken away, the whole would fall to pieces. For just because each part bears just as much as it conveniently can, and each is supported just where it requires to be and just to the necessary extent, this opposition unfolds itself, this conflict between rigidity and gravity, which constitutes the life, the manifestation of will, in the stone, becomes completely visible, and these lowest grades of the objectivity of will reveal themselves distinctly. In the same way the form of each part must not be determined arbitrarily, but by its end, and its relation to the whole. The column is the simplest form of support, determined simply by its end: the twisted column is tasteless; the four-cornered pillar is in fact not so simple as the round column, though it happens that it is easier to make it. The forms also of frieze, rafter, roof, and dome are entirely determined by their immediate end, and explain themselves from it. The decoration of capitals, &c., belongs to sculpture, not to architecture, which admits it merely as extraneous ornament, and could dispense with it. According to what has been said, it is absolutely necessary, in order to understand the æsthetic satisfaction afforded by a work of architecture, to have immediate knowledge through perception of its matter as regards its weight, rigidity, and cohesion, and our pleasure in such a work would suddenly be very much diminished by the discovery that the material used was pumice-stone; for then it would appear to us as a kind of sham building. We would be affected in almost the same way if we were told that it was made of wood, when we had supposed it to be of stone, just because this alters and destroys the relation between rigidity and gravity, and consequently the significance and necessity of all the parts, for these natural forces reveal themselves in a far weaker degree in a wooden building. Therefore no real work of architecture as a fine art can be made of wood, although it assumes all forms so easily; this can only be explained by our theory. If we were distinctly told that a building, the sight of which gave us pleasure, was made of different kinds of material of very unequal weight and consistency, but not distinguishable to the eye, the whole

building would become as utterly incapable of affording us pleasure as a poem in an unknown language. All this proves that architecture does not affect us mathematically, but also dynamically, and that what speaks to us through it, is not mere form and symmetry, but rather those fundamental forces of nature, those first Ideas, those lowest grades of the objectivity of will. The regularity of the building and its parts is partly produced by the direct adaptation of each member to the stability of the whole, partly it serves to facilitate the survey and comprehension of the whole, and finally, regular figures to some extent enhance the beauty because they reveal the constitution of space as such. But all this is of subordinate value and necessity, and by no means the chief concern; indeed, symmetry is not invariably demanded, as ruins are still beautiful.

Works of architecture have further quite a special relation to light; they gain a double beauty in the full sunshine, with the blue sky as a background, and again they have quite a different effect by moonlight. Therefore, when a beautiful work of architecture is to be erected, special attention is always paid to the effects of the light and to the climate. The reason of all this is, indeed, principally that all the parts and their relations are only made clearly visible by a bright, strong light; but besides this I am of opinion that it is the function of architecture to reveal the nature of light just as it reveals that of things so opposite to it as gravity and rigidity. For the light is intercepted, confined, and reflected by the great opaque, sharply outlined, and variously formed masses of stone, and thus it unfolds its nature and qualities in the purest and clearest way, to the great pleasure of the beholders, for light is the most joy-giving of things, as the condition and the objective correlative of the most perfect kind of knowledge of perception.

Now, because the Ideas which architecture brings to clear perception, are the lowest grades of the objectivity of will, and consequently their objective significance, which architecture reveals to us, is comparatively small; the æsthetic pleasure of looking at a beautiful building in a good light will lie, not so much in the comprehension of the Idea, as in the subjective correlative which accompanies this comprehension; it will consist pre-eminently in the fact that the beholder, set free from the kind of knowledge that belongs to the individual, and which serves the will and follows the principle of sufficient reason, is raised to that of the pure subject of knowing free from will. It will consist then principally in pure contemplation itself, free from all the suffering of will and of individuality.

In this respect the opposite of architecture, and the other extreme of the series of the fine arts, is the drama, which brings to knowledge the most significant Ideas. Therefore in the æsthetic pleasure afforded by the drama the objective side is throughout predominant.

Architecture has this distinction from plastic art and poetry: it does not give us a copy but the thing itself. It does not repeat, as they do, the known Idea, so that the artist lends his eyes to the beholder, but in it the artist merely presents the object to the beholder, and facilitates for him the comprehension of the Idea by bringing the actual, individual object to a distinct and complete expression of its nature.

Unlike the works of the other arts, those of architecture are very seldom executed for purely æsthetic ends. These are generally subordinated to other useful ends which are foreign to art itself. Thus the great merit of the architect consists in achieving and attaining the pure æsthetic ends, in spite of their subordination to other ends which are foreign to them. This he does by cleverly adapting them in a variety of ways to the arbitrary ends in view, and by rightly judging which form of æsthetical architectonic beauty is compatible and may be associated with a temple, which with a palace, which with a prison, and so forth. The more a harsh climate increases these demands of necessity and utility, determines them definitely, and prescribes them more inevitably, the less free play has beauty in architecture. In the mild climate of India, Egypt, Greece, and Rome, where the demands of necessity were fewer and less definite, architecture could follow its æsthetic ends with the greatest freedom. But under a northern sky this was sorely hindered. Here, when caissons, pointed roofs and towers were what was demanded, architecture could only unfold its own beauty within very narrow limits, and therefore it was obliged to make amends by resorting all the more to the borrowed ornaments of sculpture, as is seen in Gothic architecture.

We thus see that architecture is greatly restricted by the demands of necessity and utility; but on the other hand it has in them a very powerful support, for, on account of the magnitude and costliness of its works, and the narrow sphere of its æsthetic effect, it could not continue to exist merely as a fine art, if it had not also, as a useful and necessary profession, a firm and honourable place among the occupations of men. It is the want of this that prevents another art from taking its place beside architecture as a sister art, although in an æsthetical point of view it is quite properly to be classed

along with it as its counterpart; I mean artistic arrangements of water. For what architecture accomplishes for the Idea of gravity when it appears in connection with that of rigidity, hydraulics accomplishes for the same Idea, when it is connected with fluidity, *i.e.*, formlessness, the greatest mobility and transparency. Leaping waterfalls foaming and tumbling over rocks, cataracts dispersed into floating spray, springs gushing up as high columns of water, and clear reflecting lakes, reveal the Ideas of fluid and heavy matter, in precisely the same way as the works of architecture unfold the Ideas of rigid matter. Artistic hydraulics, however, obtains no support from practical hydraulics, for, as a rule, their ends cannot be combined; yet, in exceptional cases, this happens; for example, in the Cascata di Trevi at Rome.[52]

§ 44. What the two arts we have spoken of accomplish for these lowest grades of the objectivity of will, is performed for the higher grades of vegetable nature by artistic horticulture. The landscape beauty of a scene consists, for the most part, in the multiplicity of natural objects which are present in it, and then in the fact that they are clearly separated, appear distinctly, and yet exhibit a fitting connection and alternation. These two conditions are assisted and promoted by landscape-gardening, but it has by no means such a mastery over its material as architecture, and therefore its effect is limited. The beauty with which it is concerned belongs almost exclusively to nature; it has done little for it; and, on the other hand, it can do little against unfavourable nature, and when nature works, not for it, but against it, its achievements are small.

The vegetable world offers itself everywhere for æsthetic enjoyment without the medium of art; but so far as it is an object of art, it belongs principally to landscape-painting; to the province of which all the rest of unconscious nature also belongs. In paintings of still life, and of mere architecture, ruins, interiors of churches, &c., the subjective side of æsthetic pleasure is predominant, *i.e.*, our satisfaction does not lie principally in the direct comprehension of the represented Ideas, but rather in the subjective correlative of this comprehension, pure, will-less knowing. For, because the painter lets us see these things through his eyes, we at once receive a sympathetic and reflected sense of the deep spiritual peace and absolute silence of the will, which were necessary in order to enter with knowledge so entirely into these lifeless objects, and comprehend them with such love, *i.e.*, in this case with such a degree of objectivity. The effect of landscape-

painting proper is indeed, as a whole, of this kind; but because the Ideas expressed are more distinct and significant, as higher grades of the objectivity of will, the objective side of æsthetic pleasure already comes more to the front and assumes as much importance as the subjective side. Pure knowing as such is no longer the paramount consideration, for we are equally affected by the known Platonic Idea, the world as idea at an important grade of the objectification of will.

But a far higher grade is revealed by animal painting and sculpture. Of the latter we have some important antique remains; for example, horses at Venice, on Monte Cavallo, and on the Elgin Marbles, also at Florence in bronze and marble; the ancient boar, howling wolves, the lions in the arsenal at Venice, also in the Vatican a whole room almost filled with ancient animals, &c. In these representations the objective side of æsthetic pleasure obtains a marked predominance over the subjective. The peace of the subject which knows these Ideas, which has silenced its own will, is indeed present, as it is in all æsthetic contemplation; but its effect is not felt, for we are occupied with the restlessness and impetuosity of the will represented. It is that very will, which constitutes our own nature, that here appears to us in forms, in which its manifestation is not, as in us, controlled and tempered by intellect, but exhibits itself in stronger traits, and with a distinctness that borders on the grotesque and monstrous. For this very reason there is no concealment; it is free, naïve, open as the day, and this is the cause of our interest in animals. The characteristics of species appeared already in the representation of plants, but showed itself only in the forms; here it becomes much more distinct, and expresses itself not only in the form, but in the action, position, and mien, yet always merely as the character of the species, not of the individual. This knowledge of the Ideas of higher grades, which in painting we receive through extraneous means, we may gain directly by the pure contemplative perception of plants, and observation of beasts, and indeed of the latter in their free, natural, and unrestrained state. The objective contemplation of their manifold and marvellous forms, and of their actions and behaviour, is an instructive lesson from the great book of nature, it is a deciphering of the true *signatura rerum*.[53] We see in them the manifold grades and modes of the manifestation of will, which in all beings of one and the same grade, wills always in the same way, which objectifies itself as life, as existence in such endless variety, and such different forms, which are all adaptations to the

different external circumstances, and may be compared to many variations on the same theme. But if we had to communicate to the observer, for reflection, and in a word, the explanation of their inner nature, it would be best to make use of that Sanscrit formula which occurs so often in the sacred books of the Hindoos, and is called Mahavakya, i.e., the great word: "*Tat twam asi*," which means, "this living thing art thou."

§ 45. The great problem of historical painting and sculpture is to express directly and for perception the Idea in which the will reaches the highest grade of its objectification. The objective side of the pleasure afforded by the beautiful is here always predominant, and the subjective side has retired into the background. It is further to be observed that at the next grade below this, animal painting, the characteristic is entirely one with the beautiful; the most characteristic lion, wolf, horse, sheep, or ox, was always the most beautiful also. The reason of this is that animals have only the character of their species, no individual character. In the representation of men the character of the species is separated from that of the individual; the former is now called beauty (entirely in the objective sense), but the latter retains the name, character, or expression, and the new difficulty arises of representing both, at once and completely, in the same individual.

Human beauty is an objective expression, which means the fullest objectification of will at the highest grade at which it is knowable, the Idea of man in general, completely expressed in the sensible form. But however much the objective side of the beautiful appears here, the subjective side still always accompanies it. And just because no object transports us so quickly into pure æsthetic contemplation, as the most beautiful human countenance and form, at the sight of which we are instantly filled with unspeakable satisfaction, and raised above ourselves and all that troubles us; this is only possible because this most distinct and purest knowledge of will raises us most easily and quickly to the state of pure knowing, in which our personality, our will with its constant pain, disappears, so long as the pure æsthetic pleasure lasts. Therefore it is that Goethe says: "No evil can touch him who looks on human beauty; he feels himself at one with himself and with the world." That a beautiful human form is produced by nature must be explained in this way. At this its highest grade the will objectifies itself in an individual; and therefore through circumstances and its own power it completely overcomes all the hindrances and opposition which the phenomena of the lower grades present to it. Such are the forces of nature,

from which the will must always first extort and win back the matter that belongs to all its manifestations. Further, the phenomenon of will at its higher grades always has multiplicity in its form. Even the tree is only a systematic aggregate of innumerably repeated sprouting fibres. This combination assumes greater complexity in higher forms, and the human body is an exceedingly complex system of different parts, each of which has a peculiar life of its own, *vita propria*, subordinate to the whole. Now that all these parts are in the proper fashion subordinate to the whole, and co-ordinate to each other, that they all work together harmoniously for the expression of the whole, nothing superfluous, nothing restricted; all these are the rare conditions, whose result is beauty, the completely expressed character of the species. So is it in nature. But how in art? One would suppose that art achieved the beautiful by imitating nature. But how is the artist to recognise the perfect work which is to be imitated, and distinguish it from the failures, if he does not anticipate the beautiful *before experience*? And besides this, has nature ever produced a human being perfectly beautiful in all his parts? It has accordingly been thought that the artist must seek out the beautiful parts, distributed among a number of different human beings, and out of them construct a beautiful whole; a perverse and foolish opinion. For it will be asked, how is he to know that just these forms and not others are beautiful? We also see what kind of success attended the efforts of the old German painters to achieve the beautiful by imitating nature. Observe their naked figures. No knowledge of the beautiful is possible purely *a posteriori*, and from mere experience; it is always, at least in part, *a priori*, although quite different in kind, from the forms of the principle of sufficient reason, of which we are conscious *a priori*. These concern the universal form of phenomena as such, as it constitutes the possibility of knowledge in general, the universal *how* of all phenomena, and from this knowledge proceed mathematics and pure natural science. But this other kind of knowledge *a priori*, which makes it possible to express the beautiful, concerns, not the form but the content of phenomena, not the *how* but the *what* of the phenomenon. That we all recognise human beauty when we see it, but that in the true artist this takes place with such clearness that he shows it as he has never seen it, and surpasses nature in his representation; this is only possible because *we ourselves are* the will whose adequate objectification at its highest grade is here to be judged and discovered. Thus alone have we in fact an

anticipation of that which nature (which is just the will that constitutes our own being) strives to express. And in the true genius this anticipation is accompanied by so great a degree of intelligence that he recognises the Idea in the particular thing, and thus, as it were, *understands the half-uttered speech of nature*, and articulates clearly what she only stammered forth. He expresses in the hard marble that beauty of form which in a thousand attempts she failed to produce, he presents it to nature, saying, as it were, to her, "That is what you wanted to say!" And whoever is able to judge replies, "Yes, that is it." Only in this way was it possible for the genius of the Greeks to find the type of human beauty and establish it as a canon for the school of sculpture; and only by virtue of such an anticipation is it possible for all of us to recognise beauty, when it has actually been achieved by nature in the particular case. This anticipation is the *Ideal*. It is the *Idea* so far as it is known *a priori*, at least half, and it becomes practical for art, because it corresponds to and completes what is given *a posteriori* through nature. The possibility of such an anticipation of the beautiful *a priori* in the artist, and of its recognition *a posteriori* by the critic, lies in the fact that the artist and the critic are themselves the "in-itself" of nature, the will which objectifies itself. For, as Empedocles said, like can only be known by like: only nature can understand itself: only nature can fathom itself: but only spirit also can understand spirit.[54]

The opinion, which is absurd, although expressed by the Socrates of Xenophon (Stobæi Floril, vol. ii. p. 384) that the Greeks discovered the established ideal of human beauty empirically, by collecting particular beautiful parts, uncovering and noting here a knee, there an arm, has an exact parallel in the art of poetry. The view is entertained, that Shakespeare, for example, observed, and then gave forth from his own experience of life, the innumerable variety of the characters in his dramas, so true, so sustained, so profoundly worked out. The impossibility and absurdity of such an assumption need not be dwelt upon. It is obvious that the man of genius produces the works of poetic art by means of an anticipation of what is characteristic, just as he produces the works of plastic and pictorial art by means of a prophetic anticipation of the beautiful; yet both require experience as a pattern or model, for thus alone can that which is dimly known *a priori* be called into clear consciousness, and an intelligent representation of it becomes possible.

Human beauty was explained above as the fullest objectification of will at the highest grade at which it is knowable. It expresses itself through the form; and this lies in space alone, and has no necessary connection with time, as, for example, motion has. Thus far then we may say: the adequate objectification of will through a merely spatial phenomenon is beauty, in the objective sense. A plant is nothing but such a merely spatial phenomenon of will; for no motion, and consequently no relation to time (regarded apart from its development), belongs to the expression of its nature; its mere form expresses its whole being and displays it openly. But brutes and men require, further, for the full revelation of the will which is manifested in them, a series of actions, and thus the manifestation in them takes on a direct relation to time. All this has already been explained in the preceding book; it is related to what we are considering at present in the following way. As the merely spatial manifestation of will can objectify it fully or defectively at each definite grade, — and it is this which constitutes beauty or ugliness, — so the temporal objectification of will, *i.e.*, the action, and indeed the direct action, the movement, may correspond to the will, which objectifies itself in it, purely and fully without foreign admixture, without superfluity, without defect, only expressing exactly the act of will determined in each case; — or the converse of all this may occur. In the first case the movement is made with *grace*, in the second case without it. Thus as beauty is the adequate representation of will generally, through its merely spatial manifestation; *grace* is the adequate representation of will through its temporal manifestation, that is to say, the perfectly accurate and fitting expression of each act of will, through the movement and position which objectify it. Since movement and position presuppose the body, Winckelmann's expression is very true and suitable, when he says, "Grace is the proper relation of the acting person to the action" (Works, vol. i. p. 258). It is thus evident that beauty may be attributed to a plant, but no grace, unless in a figurative sense; but to brutes and men, both beauty and grace. Grace consists, according to what has been said, in every movement being performed, and every position assumed, in the easiest, most appropriate and convenient way, and therefore being the pure, adequate expression of its intention, or of the act of will, without any superfluity, which exhibits itself as aimless, meaningless bustle, or as wooden stiffness. Grace presupposes as its condition a true proportion of all the limbs, and a symmetrical, harmonious figure; for complete ease and evident appropriateness of all

positions and movements are only possible by means of these. Grace is therefore never without a certain degree of beauty of person. The two, complete and united, are the most distinct manifestation of will at the highest grade of its objectification.

It was mentioned above that in order rightly to portray man, it is necessary to separate the character of the species from that of the individual, so that to a certain extent every man expresses an Idea peculiar to himself, as was said in the last book. Therefore the arts whose aim is the representation of the Idea of man, have as their problem, not only beauty, the character of the species, but also the character of the individual, which is called, *par excellence*, *character*. But this is only the case in so far as this character is to be regarded, not as something accidental and quite peculiar to the man as a single individual, but as a side of the Idea of humanity which is specially apparent in this individual, and the representation of which is therefore of assistance in revealing this Idea. Thus the character, although as such it is individual, must yet be Ideal, that is, its significance in relation to the Idea of humanity generally (the objectifying of which it assists in its own way) must be comprehended and expressed with special prominence. Apart from this the representation is a portrait, a copy of the individual as such, with all his accidental qualities. And even the portrait ought to be, as Winckelmann says, the ideal of the individual.

That *character* which is to be ideally comprehended, as the prominence of a special side of the Idea of humanity, expresses itself visibly, partly through permanent physiognomy and bodily form, partly through passing emotion and passion, the reciprocal modification of knowing and willing by each other, which is all exhibited in the mien and movements. Since the individual always belongs to humanity, and, on the other hand, humanity always reveals itself in the individual with what is indeed peculiar ideal significance, beauty must not be destroyed by character nor character by beauty. For if the character of the species is annulled by that of the individual, the result is caricature; and if the character of the individual is annulled by that of the species, the result is an absence of meaning. Therefore the representation which aims at beauty, as sculpture principally does, will yet always modify this (the character of the species), in some respect, by the individual character, and will always express the Idea of man in a definite individual manner, giving prominence to a special side of it. For the human individual as such has to a certain extent the dignity of a

special Idea, and it is essential to the Idea of man that it should express itself in individuals of special significance. Therefore we find in the works of the ancients, that the beauty distinctly comprehended by them, is not expressed in one form, but in many forms of different character. It is always apprehended, as it were, from a different side, and expressed in one way in Apollo, in another way in Bacchus, in another in Hercules, in another in Antinous; indeed the characteristic may limit the beautiful, and finally extend even to hideousness, in the drunken Silenus, in the Faun, &c. If the characteristic goes so far as actually to annul the character of the species, if it extends to the unnatural, it becomes caricature. But we can far less afford to allow grace to be interfered with by what is characteristic than even beauty, for graceful position and movement are demanded for the expression of the character also; but yet it must be achieved in the way which is most fitting, appropriate, and easy for the person. This will be observed, not only by the sculptor and the painter, but also by every good actor; otherwise caricature will appear here also as grimace or distortion.

In sculpture, beauty and grace are the principal concern. The special character of the mind, appearing in emotion, passion, alternations of knowing and willing, which can only be represented by the expression of the countenance and the gestures, is the peculiar sphere of *painting*. For although eyes and colour, which lie outside the province of sculpture, contribute much to beauty, they are yet far more essential to character. Further, beauty unfolds itself more completely when it is contemplated from various points of view; but the expression, the character, can only be completely comprehended from *one* point of view.

Because beauty is obviously the chief aim of sculpture, Lessing tried to explain the fact that the *Laocoon does not cry out*, by saying that crying out is incompatible with beauty. The Laocoon formed for Lessing the theme, or at least the text of a work of his own, and both before and after him a great deal has been written on the subject. I may therefore be allowed to express my views about it in passing, although so special a discussion does not properly belong to the scheme of this work, which is throughout concerned with what is general.

§ 46. That Laocoon, in the celebrated group, does not cry out is obvious, and the universal and ever-renewed surprise at this must be occasioned by the fact that any of us would cry out if we were in his place. And nature demands that it should be so; for in the case of the acutest physical pain,

and the sudden seizure by the greatest bodily fear, all reflection, that might have inculcated silent endurance, is entirely expelled from consciousness, and nature relieves itself by crying out, thus expressing both the pain and the fear, summoning the deliverer and terrifying the assailer. Thus Winckelmann missed the expression of crying out; but as he wished to justify the artist he turned Laocoon into a Stoic, who considered it beneath his dignity to cry out *secundum naturam*, but added to his pain the useless constraint of suppressing all utterance of it. Winckelmann therefore sees in him "the tried spirit of a great man, who writhes in agony, and yet seeks to suppress the utterance of his feeling, and to lock it up in himself. He does not break forth into loud cries, as in Virgil, but only anxious sighs escape him," &c. (Works, vol. vii. p. 98, and at greater length in vol. vi. p. 104). Now Lessing criticised this opinion of Winckelmann's in his Laocoon, and improved it in the way mentioned above. In place of the psychological he gave the purely æsthetic reason that beauty, the principle of ancient art, does not admit of the expression of crying out. Another argument which he added to this, that a merely passing state incapable of duration ought not to be represented in motionless works of art, has a hundred examples of most excellent figures against it, which are fixed in merely transitory movements, dancing, wrestling, catching, &c. Indeed Goethe, in the essay on the Laocoon, which opens the Propylaen (p. 8), holds that the choice of such a merely fleeting movement is absolutely necessary. In our own day Hirt (Horen, 1797, tenth St.) finally decided the point, deducing everything from the highest truth of expression, that Laocoon does not cry out, because he can no longer do so, as he is at the point of death from choking. Lastly, Fernow ("Römische Studien," vol. i. p. 246) expounded and weighed all these opinions; he added, however, no new one of his own, but combined these three eclectically.

I cannot but wonder that such thoughtful and acute men should laboriously bring far-fetched and insufficient reasons, should resort to psychological and physiological arguments, to explain a matter the reason of which lies so near at hand, and is obvious at once to the unprejudiced; and especially I wonder that Lessing, who came so near the true explanation, should yet have entirely missed the real point.

Before all psychological and physiological inquiries as to whether Laocoon would cry out in his position or not (and I certainly affirm that he

would), it must be decided as regards the group in question, that crying out ought not to be expressed in it, for the simple reason that its expression lies quite outside the province of sculpture. A shrieking Laocoon could not be produced in marble, but only a figure with the mouth open vainly endeavouring to shriek; a Laocoon whose voice has stuck in his throat, *vox faucibus haesit*. The essence of shrieking, and consequently its effect upon the onlooker, lies entirely in sound; not in the distortion of the mouth. This phenomenon, which necessarily accompanies shrieking, derives motive and justification only from the sound produced by means of it; then it is permissible and indeed necessary, as characteristic of the action, even though it interferes with beauty. But in plastic art, to which the representation of shrieking is quite foreign and impossible, it would be actual folly to represent the medium of violent shrieking, the distorted mouth, which would disturb all the features and the remainder of the expression; for thus at the sacrifice of many other things the means would be represented, while its end, the shrieking itself, and its effect upon our feelings, would be left out. Nay more, there would be produced the spectacle of a continuous effort without effect, which is always ridiculous, and may really be compared to what happened when some one for a joke stopped the horn of a night watchman with wax while he was asleep, and then awoke him with the cry of fire, and amused himself by watching his vain endeavours to blow the horn. When, on the other hand, the expression of shrieking lies in the province of poetic or histrionic art, it is quite admissible, because it helps to express the truth, *i.e.*, the complete expression of the Idea. Thus it is with poetry, which claims the assistance of the imagination of the reader, in order to enable it to represent things perceptibly. Therefore Virgil makes Laocoon cry out like the bellowing of an ox that has broken loose after being struck by the axe; and Homer (Il. xx. 48-53) makes Mars and Minerva shriek horribly, without derogating from their divine dignity or beauty. The same with acting; Laocoon on the stage would certainly have to shriek. Sophocles makes Philoctetus cry out, and, on the ancient stage at any rate, he must actually have done so. As a case in point, I remember having seen in London the great actor Kemble play in a piece called Pizarro, translated from the German. He took the part of the American, a half-savage, but of very noble character. When he was wounded he cried out loudly and wildly, which had a great and admirable effect, for it was exceedingly characteristic and therefore assisted the truth

of the representation very much. On the other hand, a painted or sculptured model of a man shrieking, would be much more absurd than the painted music which is censured in Goethe's Propylaen. For shrieking does far more injury to the expression and beauty of the whole than music, which at the most only occupies the hands and arms, and is to be looked upon as an occupation characteristic of the person; indeed thus far it may quite rightly be painted, as long as it demands no violent movement of the body, or distortion of the mouth: for example, St. Cecilia at the organ, Raphael's violin-player in the Sciarra Gallery at Rome, and others. Since then, on account of the limits of the art, the pain of Laocoon must not be expressed by shrieking, the artist was obliged to employ every other expression of pain; this he has done in the most perfect manner, as is ably described by Winckelmann (Works, vol. vi. p. 104), whose admirable account thus retains its full value and truth, as soon as we abstract from the stoical view which underlies it.[55]

§ 47. Because beauty accompanied with grace is the principal object of sculpture, it loves nakedness, and allows clothing only so far as it does not conceal the form. It makes use of drapery, not as a covering, but as a means of exhibiting the form, a method of exposition that gives much exercise to the understanding, for it can only arrive at a perception of the cause, the form of the body, through the only directly given effect, the drapery. Thus to a certain extent drapery is in sculpture what fore-shortening is in painting. Both are suggestions, yet not symbolical, but such that, if they are successful, they force the understanding directly to perceive what is suggested, just as if it were actually given.

I may be allowed, in passing, to insert here a comparison that is very pertinent to the arts we are discussing. It is this: as the beautiful bodily form is seen to the greatest advantage when clothed in the lightest way, or indeed without any clothing at all, and therefore a very handsome man, if he had also taste and the courage to follow it, would go about almost naked, clothed only after the manner of the ancients; so every one who possesses a beautiful and rich mind will always express himself in the most natural, direct, and simple way, concerned, if it be possible, to communicate his thoughts to others, and thus relieve the loneliness that he must feel in such a world as this. And conversely, poverty of mind, confusion, and perversity of thought, will clothe itself in the most far-fetched expressions and the

obscurest forms of speech, in order to wrap up in difficult and pompous phraseology small, trifling, insipid, or commonplace thoughts; like a man who has lost the majesty of beauty, and trying to make up for the deficiency by means of clothing, seeks to hide the insignificance or ugliness of his person under barbaric finery, tinsel, feathers, ruffles, cuffs, and mantles. Many an author, if compelled to translate his pompous and obscure book into its little clear content, would be as utterly spoilt as this man if he had to go naked.

§ 48. *Historical painting* has for its principal object, besides beauty and grace, character. By character we mean generally, the representation of will at the highest grade of its objectification, when the individual, as giving prominence to a particular side of the Idea of humanity, has special significance, and shows this not merely by his form, but makes it visible in his bearing and occupation, by action of every kind, and the modifications of knowing and willing that occasion and accompany it. The Idea of man must be exhibited in these circumstances, and therefore the unfolding of its many-sidedness must be brought before our eyes by means of representative individuals, and these individuals can only be made visible in their significance through various scenes, events, and actions. This is the endless problem of the historical painter, and he solves it by placing before us scenes of life of every kind, of greater or less significance. No individual and no action can be without significance; in all and through all the Idea of man unfolds itself more and more. Therefore no event of human life is excluded from the sphere of painting. It is thus a great injustice to the excellent painters of the Dutch school, to prize merely their technical skill, and to look down upon them in other respects, because, for the most part, they represent objects of common life, whereas it is assumed that only the events of the history of the world, or the incidents of biblical story, have significance. We ought first to bethink ourselves that the inward significance of an action is quite different from its outward significance, and that these are often separated from each other. The outward significance is the importance of an action in relation to its result for and in the actual world; thus according to the principle of sufficient reason. The inward significance is the depth of the insight into the Idea of man which it reveals, in that it brings to light sides of that Idea which rarely appear, by making individuals who assert themselves distinctly and decidedly, disclose their peculiar characteristics by means of appropriately arranged circumstances.

Only the inward significance concerns art; the outward belongs to history. They are both completely independent of each other; they may appear together, but may each appear alone. An action which is of the highest significance for history may in inward significance be a very ordinary and common one; and conversely, a scene of ordinary daily life may be of great inward significance, if human individuals, and the inmost recesses of human action and will, appear in it in a clear and distinct light. Further, the outward and the inward significance of a scene may be equal and yet very different. Thus, for example, it is all the same, as far as inward significance is concerned, whether ministers discuss the fate of countries and nations over a map, or boors wrangle in a beer-house over cards and dice, just as it is all the same whether we play chess with golden or wooden pieces. But apart from this, the scenes and events that make up the life of so many millions of men, their actions, their sorrows, their joys, are on that account important enough to be the object of art, and by their rich variety they must afford material enough for unfolding the many-sided Idea of man. Indeed the very transitoriness of the moment which art has fixed in such a picture (now called *genre*-painting) excites a slight and peculiar sensation; for to fix the fleeting, ever-changing world in the enduring picture of a single event, which yet represents the whole, is an achievement of the art of painting by which it seems to bring time itself to a standstill, for it raises the individual to the Idea of its species. Finally, the historical and outwardly significant subjects of painting have often the disadvantage that just what is significant in them cannot be presented to perception, but must be arrived at by thought. In this respect the nominal significance of the picture must be distinguished from its real significance. The former is the outward significance, which, however, can only be reached as a conception; the latter is that side of the Idea of man which is made visible to the onlooker in the picture. For example, Moses found by the Egyptian princess is the nominal significance of a painting; it represents a moment of the greatest importance in history; the real significance, on the other hand, that which is really given to the onlooker, is a foundling child rescued from its floating cradle by a great lady, an incident which may have happened more than once. The costume alone can here indicate the particular historical case to the learned; but the costume is only of importance to the nominal significance, and is a matter of indifference to the real significance; for the latter knows only the human being as such, not the arbitrary forms. Subjects

taken from history have no advantage over those which are taken from mere possibility, and which are therefore to be called, not individual, but merely general. For what is peculiarly significant in the former is not the individual, not the particular event as such, but the universal in it, the side of the Idea of humanity which expresses itself through it. But, on the other hand, definite historical subjects are not on this account to be rejected, only the really artistic view of such subjects, both in the painter and in the beholder, is never directed to the individual particulars in them, which properly constitute the historical, but to the universal which expresses itself in them, to the Idea. And only those historical subjects are to be chosen the chief point of which can actually be represented, and not merely arrived at by thought, otherwise the nominal significance is too remote from the real; what is merely thought in connection with the picture becomes of most importance, and interferes with what is perceived. If even on the stage it is not right that the chief incident of the plot should take place behind the scenes (as in French tragedies), it is clearly a far greater fault in a picture. Historical subjects are distinctly disadvantageous only when they confine the painter to a field which has not been chosen for artistic but for other reasons, and especially when this field is poor in picturesque and significant objects — if, for example, it is the history of a small, isolated, capricious, hierarchical (*i.e.*, ruled by error), obscure people, like the Jews, despised by the great contemporary nations of the East and the West. Since the wandering of the tribes lies between us and all ancient nations, as the change of the bed of the ocean lies between the earth's surface as it is to-day and as it was when those organisations existed which we only know from fossil remains, it is to be regarded generally as a great misfortune that the people whose culture was to be the principal basis of our own were not the Indians or the Greeks, or even the Romans, but these very Jews. But it was especially a great misfortune for the Italian painters of genius in the fifteenth and sixteenth centuries that, in the narrow sphere to which they were arbitrarily driven for the choice of subjects, they were obliged to have recourse to miserable beings of every kind. For the New Testament, as regards its historical part, is almost more unsuitable for painting than the Old, and the subsequent history of martyrs and doctors of the church is a very unfortunate subject. Yet of the pictures, whose subject is the history or mythology of Judaism and Christianity, we must carefully distinguish those in which the peculiar, *i.e.*, the ethical spirit of Christianity is revealed for

perception, by the representation of men who are full of this spirit. These representations are in fact the highest and most admirable achievements of the art of painting; and only the greatest masters of this art succeeded in this, particularly Raphael and Correggio, and especially in their earlier pictures. Pictures of this kind are not properly to be classed as historical: for, as a rule, they represent no event, no action; but are merely groups of saints, with the Saviour himself, often still a child, with His mother, angels, &c. In their countenances, and especially in the eyes, we see the expression, the reflection, of the completest knowledge, that which is not directed to particular things, but has fully grasped the Ideas, and thus the whole nature of the world and life. And this knowledge in them, reacting upon the will, does not, like other knowledge, convey *motives* to it, but on the contrary has become a *quieter* of all will, from which proceeded the complete resignation, which is the innermost spirit of Christianity, as of the Indian philosophy; the surrender of all volition, conversion, the suppression of will, and with it of the whole inner being of this world, that is to say, salvation. Thus these masters of art, worthy of eternal praise, expressed perceptibly in their works the highest wisdom. And this is the summit of all art. It has followed the will in its adequate objectivity, the Ideas, through all its grades, in which it is affected and its nature unfolded in so many ways, first by causes, then by stimuli, and finally by motives. And now art ends with the representation of the free self-suppression of will, by means of the great peace which it gains from the perfect knowledge of its own nature.[56]

§ 49. The truth which lies at the foundation of all that we have hitherto said about art, is that the object of art, the representation of which is the aim of the artist, and the knowledge of which must therefore precede his work as its germ and source, is an Idea in Plato's sense, and never anything else; not the particular thing, the object of common apprehension, and not the concept, the object of rational thought and of science. Although the Idea and the concept have something in common, because both represent as unity a multiplicity of real things; yet the great difference between them has no doubt been made clear and evident enough by what we have said about concepts in the first book, and about Ideas in this book. I by no means wish to assert, however, that Plato really distinctly comprehended this difference; indeed many of his examples of Ideas, and his discussions of them, are applicable only to concepts. Meanwhile we leave this question alone and go on our own way, glad when we come upon traces of any great and noble

mind, yet not following his footsteps but our own aim. The *concept* is abstract, discursive, undetermined within its own sphere, only determined by its limits, attainable and comprehensible by him who has only reason, communicable by words without any other assistance, entirely exhausted by its definition. The *Idea* on the contrary, although defined as the adequate representative of the concept, is always object of perception, and although representing an infinite number of particular things, is yet thoroughly determined. It is never known by the individual as such, but only by him who has raised himself above all willing and all individuality to the pure subject of knowing. Thus it is only attainable by the man of genius, and by him who, for the most part through the assistance of the works of genius, has reached an exalted frame of mind, by increasing his power of pure knowing. It is therefore not absolutely but only conditionally communicable, because the Idea, comprehended and repeated in the work of art, appeals to every one only according to the measure of his own intellectual worth. So that just the most excellent works of every art, the noblest productions of genius, must always remain sealed books to the dull majority of men, inaccessible to them, separated from them by a wide gulf, just as the society of princes is inaccessible to the common people. It is true that even the dullest of them accept on authority recognisedly great works, lest otherwise they should argue their own incompetence; but they wait in silence, always ready to express their condemnation, as soon as they are allowed to hope that they may do so without being left to stand alone; and then their long-restrained hatred against all that is great and beautiful, and against the authors of it, gladly relieves itself; for such things never appealed to them, and for that very reason were humiliating to them. For as a rule a man must have worth in himself in order to recognise it and believe in it willingly and freely in others. On this rests the necessity of modesty in all merit, and the disproportionately loud praise of this virtue, which alone of all its sisters is always included in the eulogy of every one who ventures to praise any distinguished man, in order to appease and quiet the wrath of the unworthy. What then is modesty but hypocritical humility, by means of which, in a world swelling with base envy, a man seeks to obtain pardon for excellences and merits from those who have none? For whoever attributes to himself no merits, because he actually has none, is not modest but merely honest.

The *Idea* is the unity that falls into multiplicity on account of the temporal and spatial form of our intuitive apprehension; the *concept*, on the contrary, is the unity reconstructed out of multiplicity by the abstraction of our reason; the latter may be defined as *unitas post rem*, the former as *unitas ante rem*. Finally, we may express the distinction between the Idea and the concept, by a comparison, thus: the *concept* is like a dead receptacle, in which, whatever has been put, actually lies side by side, but out of which no more can be taken (by analytical judgment) than was put in (by synthetical reflection); the (Platonic) *Idea*, on the other hand, develops, in him who has comprehended it, ideas which are new as regards the concept of the same name; it resembles a living organism, developing itself and possessed of the power of reproduction, which brings forth what was not put into it.

It follows from all that has been said, that the concept, useful as it is in life, and serviceable, necessary and productive as it is in science, is yet always barren and unfruitful in art. The comprehended Idea, on the contrary, is the true and only source of every work of art. In its powerful originality it is only derived from life itself, from nature, from the world, and that only by the true genius, or by him whose momentary inspiration reaches the point of genius. Genuine and immortal works of art spring only from such direct apprehension. Just because the Idea is and remains object of perception, the artist is not conscious in the abstract of the intention and aim of his work; not a concept, but an Idea floats before his mind; therefore he can give no justification of what he does. He works, as people say, from pure feeling, and unconsciously, indeed instinctively. On the contrary, imitators, mannerists, *imitatores, servum pecus*, start, in art, from the concept; they observe what pleases and affects us in true works of art; understand it clearly, fix it in a concept, and thus abstractly, and then imitate it, openly or disguisedly, with dexterity and intentionally. They suck their nourishment, like parasite plants, from the works of others, and like polypi, they become the colour of their food. We might carry comparison further, and say that they are like machines which mince fine and mingle together whatever is put into them, but can never digest it, so that the different constituent parts may always be found again if they are sought out and separated from the mixture; the man of genius alone resembles the organised, assimilating, transforming and reproducing body. For he is indeed educated and cultured by his predecessors and their works; but he is

really fructified only by life and the world directly, through the impression of what he perceives; therefore the highest culture never interferes with his originality. All imitators, all mannerists, apprehend in concepts the nature of representative works of art; but concepts can never impart inner life to a work. The age, *i.e.*, the dull multitude of every time, knows only concepts, and sticks to them, and therefore receives mannered works of art with ready and loud applause: but after a few years these works become insipid, because the spirit of the age, *i.e.*, the prevailing concepts, in which alone they could take root, have changed. Only true works of art, which are drawn directly from nature and life, have eternal youth and enduring power, like nature and life themselves. For they belong to no age, but to humanity, and as on that account they are coldly received by their own age, to which they disdain to link themselves closely, and because indirectly and negatively they expose the existing errors, they are slowly and unwillingly recognised; on the other hand, they cannot grow old, but appear to us ever fresh and new down to the latest ages. Then they are no longer exposed to neglect and ignorance, for they are crowned and sanctioned by the praise of the few men capable of judging, who appear singly and rarely in the course of ages,[57] and give in their votes, whose slowly growing number constitutes the authority, which alone is the judgment-seat we mean when we appeal to posterity. It is these successively appearing individuals, for the mass of posterity will always be and remain just as perverse and dull as the mass of contemporaries always was and always is. We read the complaints of great men in every century about the customs of their age. They always sound as if they referred to our own age, for the race is always the same. At every time and in every art, mannerisms have taken the place of the spirit, which was always the possession of a few individuals, but mannerisms are just the old cast-off garments of the last manifestation of the spirit that existed and was recognised. From all this it appears that, as a rule, the praise of posterity can only be gained at the cost of the praise of one's contemporaries, and *vice versa*.[58]

§ 50. If the aim of all art is the communication of the comprehended Idea, which through the mind of the artist appears in such a form that it is purged and isolated from all that is foreign to it, and may now be grasped by the man of weaker comprehension and no productive faculty; if further, it is forbidden in art to start from the concept, we shall not be able to consent to the intentional and avowed employment of a work of art for the

expression of a concept; this is the case in the *Allegory*. An allegory is a work of art which means something different from what it represents. But the object of perception, and consequently also the Idea, expresses itself directly and completely, and does not require the medium of something else which implies or indicates it. Thus, that which in this way is indicated and represented by something entirely different, because it cannot itself be made object of perception, is always a concept. Therefore through the allegory a conception has always to be signified, and consequently the mind of the beholder has to be drawn away from the expressed perceptible idea to one which is entirely different, abstract and not perceptible, and which lies quite outside the work of art. The picture or statue is intended to accomplish here what is accomplished far more fully by a book. Now, what we hold is the end of art, representation of a perceivable, comprehensible Idea, is not here the end. No great completeness in the work of art is demanded for what is aimed at here. It is only necessary that we should see what the thing is meant to be, for, as soon as this has been discovered, the end is reached, and the mind is now led away to quite a different kind of idea to an abstract conception, which is the end that was in view. Allegories in plastic and pictorial art are, therefore, nothing but hieroglyphics; the artistic value which they may have as perceptible representations, belongs to them not as allegories, but otherwise. That the "Night" of Correggio, the "Genius of Fame" of Hannibal Caracci, and the "Hours" of Poussin, are very beautiful pictures, is to be separated altogether from the fact that they are allegories. As allegories they do not accomplish more than a legend, indeed rather less. We are here again reminded of the distinction drawn above between the real and the nominal significance of a picture. The nominal is here the allegorical as such, for example, the "Genius of Fame." The real is what is actually represented, in this case a beautiful winged youth, surrounded by beautiful boys; this expresses an Idea. But this real significance affects us only so long as we forget the nominal, allegorical significance; if we think of the latter, we forsake the perception, and the mind is occupied with an abstract conception; but the transition from the Idea to the conception is always a fall. Indeed, that nominal significance, that allegorical intention, often injures the real significance, the perceptible truth. For example, the unnatural light in the "Night" of Correggio, which, though beautifully executed, has yet a merely allegorical motive, and is really impossible. If then an allegorical picture has artistic value, it is quite separate from and

independent of what it accomplishes as allegory. Such a work of art serves two ends at once, the expression of a conception and the expression of an Idea. Only the latter can be an end of art; the other is a foreign end, the trifling amusement of making a picture also do service as a legend, as a hieroglyphic, invented for the pleasure of those to whom the true nature of art can never appeal. It is the same thing as when a work of art is also a useful implement of some kind, in which case it also serves two ends; for example, a statue which is at the same time a candelabrum or a caryatide; or a bas-relief, which is also the shield of Achilles. True lovers of art will allow neither the one nor the other. It is true that an allegorical picture may, because of this quality, produce a vivid impression upon the feelings; but when this is the case, a legend would under the same circumstances produce the same effect. For example, if the desire of fame were firmly and lastingly rooted in the heart of a man, because he regarded it as his rightful possession, which is only withheld from him so long as he has not produced the charter of his ownership; and if the Genius of Fame, with his laurel crown, were to appear to such a man, his whole mind would be excited, and his powers called into activity; but the same effect would be produced if he were suddenly to see the word "fame," in large distinct letters on the wall. Or if a man has made known a truth, which is of importance either as a maxim for practical life, or as insight for science, but it has not been believed; an allegorical picture representing time as it lifts the veil, and discloses the naked figure of Truth, will affect him powerfully; but the same effect would be produced by the legend: "*Le temps découvre la vérité.*" For what really produces the effect here is the abstract thought, not the object of perception.

If then, in accordance with what has been said, allegory in plastic and pictorial art is a mistaken effort, serving an end which is entirely foreign to art, it becomes quite unbearable when it leads so far astray that the representation of forced and violently introduced subtilties degenerates into absurdity. Such, for example, is a tortoise, to represent feminine seclusion; the downward glance of Nemesis into the drapery of her bosom, signifying that she can see into what is hidden; the explanation of Bellori that Hannibal Carracci represents voluptuousness clothed in a yellow robe, because he wishes to indicate that her lovers soon fade and become yellow as straw. If there is absolutely no connection between the representation and the conception signified by it, founded on subsumption under the concept,

or association of Ideas; but the signs and the things signified are combined in a purely conventional manner, by positive, accidentally introduced laws; then I call this degenerate kind of allegory *Symbolism*. Thus the rose is the symbol of secrecy, the laurel is the symbol of fame, the palm is the symbol of peace, the scallop-shell is the symbol of pilgrimage, the cross is the symbol of the Christian religion. To this class also belongs all significance of mere colour, as yellow is the colour of falseness, and blue is the colour of fidelity. Such symbols may often be of use in life, but their value is foreign to art. They are simply to be regarded as hieroglyphics, or like Chinese word-writing, and really belong to the same class as armorial bearings, the bush that indicates a public-house, the key of the chamberlain, or the leather of the mountaineer. If, finally, certain historical or mythical persons, or personified conceptions, are represented by certain fixed symbols, these are properly called *emblems*. Such are the beasts of the Evangelist, the owl of Minerva, the apple of Paris, the Anchor of Hope, &c. For the most part, however, we understand by emblems those simple allegorical representations explained by a motto, which are meant to express a moral truth, and of which large collections have been made by J. Camerarius, Alciatus, and others. They form the transition to poetical allegory, of which we shall have more to say later. Greek sculpture devotes itself to the perception, and therefore it is *æsthetical*; Indian sculpture devotes itself to the conception, and therefore it is merely *symbolical*.

This conclusion in regard to allegory, which is founded on our consideration of the nature of art and quite consistent with it, is directly opposed to the opinion of Winckelmann, who, far from explaining allegory, as we do, as something quite foreign to the end of art, and often interfering with it, always speaks in favour of it, and indeed (Works, vol. i. p. 55) places the highest aim of art in the "representation of universal conceptions, and non-sensuous things." We leave it to every one to adhere to whichever view he pleases. Only the truth became very clear to me from these and similar views of Winckelmann connected with his peculiar metaphysic of the beautiful, that one may have the greatest susceptibility for artistic beauty, and the soundest judgment in regard to it, without being able to give an abstract and strictly philosophical justification of the nature of the beautiful; just as one may be very noble and virtuous, and may have a tender conscience, which decides with perfect accuracy in particular cases,

without on that account being in a position to investigate and explain in the abstract the ethical significance of action.

Allegory has an entirely different relation to poetry from that which it has to plastic and pictorial art, and although it is to be rejected in the latter, it is not only permissible, but very serviceable to the former. For in plastic and pictorial art it leads away from what is perceptibly given, the proper object of all art, to abstract thoughts; but in poetry the relation is reversed; for here what is directly given in words is the concept, and the first aim is to lead from this to the object of perception, the representation of which must be undertaken by the imagination of the hearer. If in plastic and pictorial art we are led from what is immediately given to something else, this must always be a conception, because here only the abstract cannot be given directly; but a conception must never be the source, and its communication must never be the end of a work of art. In poetry, on the contrary, the conception is the material, the immediately given, and therefore we may very well leave it, in order to call up perceptions which are quite different, and in which the end is reached. Many a conception or abstract thought may be quite indispensable to the connection of a poem, which is yet, in itself and directly, quite incapable of being perceived; and then it is often made perceptible by means of some example which is subsumed under it. This takes place in every trope, every metaphor, simile, parable, and allegory, all of which differ only in the length and completeness of their expression. Therefore, in the arts which employ language as their medium, similes and allegories are of striking effect. How beautifully Cervantes says of sleep in order to express the fact that it frees us from all spiritual and bodily suffering, "It is a mantle that covers all mankind." How beautifully Kleist expresses allegorically the thought that philosophers and men of science enlighten mankind, in the line, "Those whose midnight lamp lights the world." How strongly and sensuously Homer describes the harmful Ate when he says: "She has tender feet, for she walks not on the hard earth, but treads on the heads of men" (Il. xix. 91.) How forcibly we are struck by Menenius Agrippa's fable of the belly and the limbs, addressed to the people of Rome when they seceded. How beautifully Plato's figure of the Cave, at the beginning of the seventh book of the "Republic" to which we have already referred, expresses a very abstract philosophical dogma. The fable of Persephone is also to be regarded as a deeply significant allegory of philosophical tendency, for she became subject to the nether world by

tasting a pomegranate. This becomes peculiarly enlightening from Goethe's treatment of the fable, as an episode in the *Triumph der Empfindsamkeit*, which is beyond all praise. Three detailed allegorical works are known to me, one, open and avowed, is the incomparable "Criticon" of Balthasar Gracian. It consists of a great rich web of connected and highly ingenious allegories, that serve here as the fair clothing of moral truths, to which he thus imparts the most perceptible form, and astonishes us by the richness of his invention. The two others are concealed allegories, "Don Quixote" and "Gulliver's Travels." The first is an allegory of the life of every man, who will not, like others, be careful, merely for his own welfare, but follows some objective, ideal end, which has taken possession of his thoughts and will; and certainly, in this world, he has then a strange appearance. In the case of Gulliver we have only to take everything physical as spiritual or intellectual, in order to see what the "satirical rogue," as Hamlet would call him, meant by it. Such, then, in the poetical allegory, the conception is always the given, which it tries to make perceptible by means of a picture; it may sometimes be expressed or assisted by a painted picture. Such a picture will not be regarded as a work of art, but only as a significant symbol, and it makes no claim to pictorial, but only to poetical worth. Such is that beautiful allegorical vignette of Lavater's, which must be so heartening to every defender of truth: a hand holding a light is stung by a wasp, while gnats are burning themselves in the flame above; underneath is the motto:

"And although it singes the wings of the gnats,
Destroys their heads and all their little brains,
Light is still light;
And although I am stung by the angriest wasp,
I will not let it go."

To this class also belongs the gravestone with the burnt-out, smoking candle, and the inscription —

"When it is out, it becomes clear
Whether the candle was tallow or wax."

Finally, of this kind is an old German genealogical tree, in which the last representative of a very ancient family thus expresses his determination to live his life to the end in abstinence and perfect chastity, and therefore to let his race die out; he represents himself at the root of the high-branching tree cutting it over himself with shears. In general all those symbols referred to above, commonly called emblems, which might also be defined as short

painted fables with obvious morals, belong to this class. Allegories of this kind are always to be regarded as belonging to poetry, not to painting, and as justified thereby; moreover, the pictorial execution is here always a matter of secondary importance, and no more is demanded of it than that it shall represent the thing so that we can recognise it. But in poetry, as in plastic art, the allegory passes into the symbol if there is merely an arbitrary connection between what it presented to perception and the abstract significance of it. For as all symbolism rests, at bottom, on an agreement, the symbol has this among other disadvantages, that in time its meaning is forgotten, and then it is dumb. Who would guess why the fish is a symbol of Christianity if he did not know? Only a Champollion; for it is entirely a phonetic hieroglyphic. Therefore, as a poetical allegory, the Revelation of John stands much in the same position as the reliefs with *Magnus Deus sol Mithra*, which are still constantly being explained.

§ 51. If now, with the exposition which has been given of art in general, we turn from plastic and pictorial art to poetry, we shall have no doubt that its aim also is the revelation of the Ideas, the grades of the objectification of will, and the communication of them to the hearer with the distinctness and vividness with which the poetical sense comprehends them. Ideas are essentially perceptible; if, therefore, in poetry only abstract conceptions are directly communicated through words, it is yet clearly the intention to make the hearer perceive the Ideas of life in the representatives of these conceptions, and this can only take place through the assistance of his own imagination. But in order to set the imagination to work for the accomplishment of this end, the abstract conceptions, which are the immediate material of poetry as of dry prose, must be so arranged that their spheres intersect each other in such a way that none of them can remain in its abstract universality; but, instead of it, a perceptible representative appears to the imagination; and this is always further modified by the words of the poet according to what his intention may be. As the chemist obtains solid precipitates by combining perfectly clear and transparent fluids; the poet understands how to precipitate, as it were, the concrete, the individual, the perceptible idea, out of the abstract and transparent universality of the concepts by the manner in which he combines them. For the Idea can only be known by perception; and knowledge of the Idea is the end of art. The skill of a master, in poetry as in chemistry, enables us always to obtain the precise precipitate we intended. This end is assisted by the numerous

epithets in poetry, by means of which the universality of every concept is narrowed more and more till we reach the perceptible. Homer attaches to almost every substantive an adjective, whose concept intersects and considerably diminishes the sphere of the concept of the substantive, which is thus brought so much the nearer to perception: for example —

“Εν δ᾽ επεσ᾽ Ωκεανῳ λαμπρον φαος ἠελιοιο,

Ἑλκον νυκτα μελαιναν επι ζειδωρον αρουραν.”

(“Occidit vero in Oceanum splendidum lumen solis,

Trahens noctem nigram super almam terram.”)

And —

“Where gentle winds from the blue heavens sigh,

There stand the myrtles still, the laurel high,” —

calls up before the imagination by means of a few concepts the whole delight of a southern clime.

Rhythm and rhyme are quite peculiar aids to poetry. I can give no other explanation of their incredibly powerful effect than that our faculties of perception have received from time, to which they are essentially bound, some quality on account of which we inwardly follow, and, as it were, consent to each regularly recurring sound. In this way rhythm and rhyme are partly a means of holding our attention, because we willingly follow the poem read, and partly they produce in us a blind consent to what is read prior to any judgment, and this gives the poem a certain emphatic power of convincing independent of all reasons.

From the general nature of the material, that is, the concepts, which poetry uses to communicate the Ideas, the extent of its province is very great. The whole of nature, the Ideas of all grades, can be represented by means of it, for it proceeds according to the Idea it has to impart, so that its representations are sometimes descriptive, sometimes narrative, and sometimes directly dramatic. If, in the representation of the lower grades of the objectivity of will, plastic and pictorial art generally surpass it, because lifeless nature, and even brute nature, reveals almost its whole being in a single well-chosen moment; man, on the contrary, so far as he does not express himself by the mere form and expression of his person, but through a series of actions and the accompanying thoughts and emotions, is the principal object of poetry, in which no other art can compete with it, for here the progress or movement which cannot be represented in plastic or pictorial art just suits its purpose.

The revelation of the Idea, which is the highest grade of the objectivity of will, the representation of man in the connected series of his efforts and actions, is thus the great problem of poetry. It is true that both experience and history teach us to know man; yet oftener men than man, *i.e.*, they give us empirical notes of the behaviour of men to each other, from which we may frame rules for our own conduct, oftener than they afford us deep glimpses of the inner nature of man. The latter function, however, is by no means entirely denied them; but as often as it is the nature of mankind itself that discloses itself to us in history or in our own experience, we have comprehended our experience, and the historian has comprehended history, with artistic eyes, poetically, *i.e.*, according to the Idea, not the phenomenon, in its inner nature, not in its relations. Our own experience is the indispensable condition of understanding poetry as of understanding history; for it is, so to speak, the dictionary of the language that both speak. But history is related to poetry as portrait-painting is related to historical painting; the one gives us the true in the individual, the other the true in the universal; the one has the truth of the phenomenon, and can therefore verify it from the phenomenal, the other has the truth of the Idea, which can be found in no particular phenomenon, but yet speaks to us from them all. The poet from deliberate choice represents significant characters in significant situations; the historian takes both as they come. Indeed, he must regard and select the circumstances and the persons, not with reference to their inward and true significance, which expresses the Idea, but according to the outward, apparent, and relatively important significance with regard to the connection and the consequences. He must consider nothing in and for itself in its essential character and expression, but must look at everything in its relations, in its connection, in its influence upon what follows, and especially upon its own age. Therefore he will not overlook an action of a king, though of little significance, and in itself quite common, because it has results and influence. And, on the other hand, actions of the highest significance of particular and very eminent individuals are not to be recorded by him if they have no consequences. For his treatment follows the principle of sufficient reason, and apprehends the phenomenon, of which this principle is the form. But the poet comprehends the Idea, the inner nature of man apart from all relations, outside all time, the adequate objectivity of the thing-in-itself, at its highest grade. Even in that method of treatment which is necessary for the historian, the inner nature and

significance of the phenomena, the kernel of all these shells, can never be entirely lost. He who seeks for it, at any rate, may find it and recognise it. Yet that which is significant in itself, not in its relations, the real unfolding of the Idea, will be found far more accurately and distinctly in poetry than in history, and, therefore, however paradoxical it may sound, far more really genuine inner truth is to be attributed to poetry than to history. For the historian must accurately follow the particular event according to life, as it develops itself in time in the manifold tangled chains of causes and effects. It is, however, impossible that he can have all the data for this; he cannot have seen all and discovered all. He is forsaken at every moment by the original of his picture, or a false one substitutes itself for it, and this so constantly that I think I may assume that in all history the false outweighs the true. The poet, on the contrary, has comprehended the Idea of man from some definite side which is to be represented; thus it is the nature of his own self that objectifies itself in it for him. His knowledge, as we explained above when speaking of sculpture, is half *a priori*; his ideal stands before his mind firm, distinct, brightly illuminated, and cannot forsake him; therefore he shows us, in the mirror of his mind, the Idea pure and distinct, and his delineation of it down to the minutest particular is true as life itself.[59] The great ancient historians are, therefore, in those particulars in which their data fail them, for example, in the speeches of their heroes — poets; indeed their whole manner of handling their material approaches to the epic. But this gives their representations unity, and enables them to retain inner truth, even when outward truth was not accessible, or indeed was falsified. And as we compared history to portrait-painting, in contradistinction to poetry, which corresponds to historical painting, we find that Winckelmann's maxim, that the portrait ought to be the ideal of the individual, was followed by the ancient historians, for they represent the individual in such a way as to bring out that side of the Idea of man which is expressed in it. Modern historians, on the contrary, with few exceptions, give us in general only "a dust-bin and a lumber-room, and at the most a chronicle of the principal political events." Therefore, whoever desires to know man in his inner nature, identical in all its phenomena and developments, to know him according to the Idea, will find that the works of the great, immortal poet present a far truer, more distinct picture, than the historians can ever give. For even the best of the historians are, as poets, far from the first; and moreover their hands are tied. In this aspect the relation

between the historian and the poet may be illustrated by the following comparison. The mere, pure historian, who works only according to data, is like a man, who without any knowledge of mathematics, has investigated the relations of certain figures, which he has accidentally found, by measuring them; and the problem thus empirically solved is affected of course by all the errors of the drawn figure. The poet, on the other hand, is like the mathematician, who constructs these relations *a priori* in pure perception, and expresses them not as they actually are in the drawn figure, but as they are in the Idea, which the drawing is intended to render for the senses. Therefore Schiller says: —

“What has never anywhere come to pass,
That alone never grows old.”

Indeed I must attribute greater value to biographies, and especially to autobiographies, in relation to the knowledge of the nature of man, than to history proper, at least as it is commonly handled. Partly because in the former the data can be collected more accurately and completely than in the latter; partly, because in history proper, it is not so much men as nations and heroes that act, and the individuals who do appear, seem so far off, surrounded with such pomp and circumstance, clothed in the stiff robes of state, or heavy, inflexible armour, that it is really hard through all this to recognise the human movements. On the other hand, the life of the individual when described with truth, in a narrow sphere, shows the conduct of men in all its forms and subtilties, the excellence, the virtue, and even holiness of a few, the perversity, meanness, and knavery of most, the dissolute profligacy of some. Besides, in the only aspect we are considering here, that of the inner significance of the phenomenal, it is quite the same whether the objects with which the action is concerned, are, relatively considered, trifling or important, farm-houses or kingdoms: for all these things in themselves are without significance, and obtain it only in so far as the will is moved by them. The motive has significance only through its relation to the will, while the relation which it has as a thing to other things like itself, does not concern us here. As a circle of one inch in diameter, and a circle of forty million miles in diameter, have precisely the same geometrical properties, so are the events and the history of a village and a kingdom essentially the same; and we may study and learn to know mankind as well in the one as in the other. It is also a mistake to suppose

that autobiographies are full of deceit and dissimulation. On the contrary, lying (though always possible) is perhaps more difficult there than elsewhere. Dissimulation is easiest in mere conversation; indeed, though it may sound paradoxical, it is really more difficult even in a letter. For in the case of a letter the writer is alone, and looks into himself, and not out on the world, so that what is strange and distant does not easily approach him; and he has not the test of the impression made upon another before his eyes. But the receiver of the letter peruses it quietly in a mood unknown to the writer, reads it repeatedly and at different times, and thus easily finds out the concealed intention. We also get to know an author as a man most easily from his books, because all these circumstances act here still more strongly and permanently. And in an autobiography it is so difficult to dissimulate, that perhaps there does not exist a single one that is not, as a whole, more true, than any history that ever was written. The man who writes his own life surveys it as a whole, the particular becomes small, the near becomes distant, the distant becomes near again, the motives that influenced him shrink; he seats himself at the confessional, and has done so of his own free will; the spirit of lying does not so easily take hold of him here, for there is also in every man an inclination to truth which has first to be overcome whenever he lies, and which here has taken up a specially strong position. The relation between biography and the history of nations may be made clear for perception by means of the following comparison: History shows us mankind as a view from a high mountain shows us nature; we see much at a time, wide stretches, great masses, but nothing is distinct nor recognisable in all the details of its own peculiar nature. On the other hand, the representation of the life of the individual shows us the man, as we see nature if we go about among her trees, plants, rocks, and waters. But in landscape-painting, in which the artist lets us look at nature with his eyes, the knowledge of the Ideas, and the condition of pure will-less knowing, which is demanded by these, is made much easier for us; and, in the same way, poetry is far superior both to history and biography, in the representation of the Ideas which may be looked for in all three. For here also genius holds up to us the magic glass, in which all that is essential and significant appears before us collected and placed in the clearest light, and what is accidental and foreign is left out.[60]

The representation of the Idea of man, which is the work of the poet, may be performed, so that what is represented is also the representer. This is

the case in lyrical poetry, in songs, properly so called, in which the poet only perceives vividly his own state and describes it. Thus a certain subjectivity is essential to this kind of poetry from the nature of its object. Again, what is to be represented may be entirely different from him who represents it, as is the case in all other kinds of poetry, in which the poet more or less conceals himself behind his representation, and at last disappears altogether. In the ballad the poet still expresses to some extent his own state through the tone and proportion of the whole; therefore, though much more objective than the lyric, it has yet something subjective. This becomes less in the idyll, still less in the romantic poem, almost entirely disappears in the true epic, and even to the last vestige in the drama, which is the most objective and, in more than one respect, the completest and most difficult form of poetry. The lyrical form of poetry is consequently the easiest, and although art, as a whole, belongs only to the true man of genius, who so rarely appears, even a man who is not in general very remarkable may produce a beautiful song if, by actual strong excitement from without, some inspiration raises his mental powers; for all that is required for this is a lively perception of his own state at a moment of emotional excitement. This is proved by the existence of many single songs by individuals who have otherwise remained unknown; especially the German national songs, of which we have an exquisite collection in the "Wunderhorn;" and also by innumerable love-songs and other songs of the people in all languages; — for to seize the mood of a moment and embody it in a song is the whole achievement of this kind of poetry. Yet in the lyrics of true poets the inner nature of all mankind is reflected, and all that millions of past, present, and future men have found, or will find, in the same situations, which are constantly recurring, finds its exact expression in them. And because these situations, by constant recurrence, are permanent as man himself and always call up the same sensations, the lyrical productions of genuine poets remain through thousands of years true, powerful, and fresh. But if the poet is always the universal man, then all that has ever moved a human heart, all that human nature in any situation has ever produced from itself, all that dwells and broods in any human breast — is his theme and his material, and also all the rest of nature. Therefore the poet may just as well sing of voluptuousness as of mysticism, be Anacreon or Angelus Silesius, write tragedies or comedies, represent the sublime or the common mind — according to humour or vocation. And no

one has the right to prescribe to the poet what he ought to be — noble and sublime, moral, pious, Christian, one thing or another, still less to reproach him because he is one thing and not another. He is the mirror of mankind, and brings to its consciousness what it feels and does.

If we now consider more closely the nature of the lyric proper, and select as examples exquisite and pure models, not those that approach in any way to some other form of poetry, such as the ballad, the elegy, the hymn, the epigram, &c., we shall find that the peculiar nature of the lyric, in the narrowest sense, is this: It is the subject of will, *i.e.*, his own volition, which the consciousness of the singer feels; often as a released and satisfied desire (joy), but still oftener as a restricted desire (grief), always as an emotion, a passion, a moved frame of mind. Besides this, however, and along with it, by the sight of surrounding nature, the singer becomes conscious of himself as the subject of pure, will-less knowing, whose unbroken blissful peace now appears, in contrast to the stress of desire which is always restricted and always needy. The feeling of this contrast, this alternation, is really what the lyric as a whole expresses, and what principally constitutes the lyrical state of mind. In it pure knowing comes to us, as it were, to deliver us from desire and its stain; we follow, but only for an instant; desire, the remembrance of our own personal ends, tears us anew from peaceful contemplation; yet ever again the next beautiful surrounding in which the pure will-less knowledge presents itself to us, allures us away from desire. Therefore, in the lyric and the lyrical mood, desire (the personal interest of the ends), and pure perception of the surrounding presented, are wonderfully mingled with each other; connections between them are sought for and imagined; the subjective disposition, the affection of the will, imparts its own hue to the perceived surrounding, and conversely, the surroundings communicate the reflex of their colour to the will. The true lyric is the expression of the whole of this mingled and divided state of mind. In order to make clear by examples this abstract analysis of a frame of mind that is very far from all abstraction, any of the immortal songs of Goethe may be taken. As specially adapted for this end I shall recommend only a few: “The Shepherd’s Lament,” “Welcome and Farewell,” “To the Moon,” “On the Lake,” “Autumn;” also the songs in the “Wunderhorn” are excellent examples; particularly the one which begins, “O Bremen, I must now leave thee.” As a comical and happy parody of the lyrical character a song of Voss strikes me as remarkable. It describes the feeling of a drunk

plumber falling from a tower, who observes in passing that the clock on the tower is at half-past eleven, a remark which is quite foreign to his condition, and thus belongs to knowledge free from will. Whoever accepts the view that has been expressed of the lyrical frame of mind, will also allow, that it is the sensuous and poetical knowledge of the principle which I established in my essay on the Principle of Sufficient Reason, and have also referred to in this work, that the identity of the subject of knowing with that of willing may be called the miracle κατʹ εξοχην; so that the poetical effect of the lyric rests finally on the truth of that principle. In the course of life these two subjects, or, in popular language, head and heart, are ever becoming further apart; men are always separating more between their subjective feeling and their objective knowledge. In the child the two are still entirely blended together; it scarcely knows how to distinguish itself from its surroundings, it is at one with them. In the young man all perception chiefly affects feeling and mood, and even mingles with it, as Byron very beautifully expresses —

"I live not in myself, but I become
Portion of that around me; and to me
High mountains are a feeling."

This is why the youth clings so closely to the perceptible and outward side of things; this is why he is only fit for lyrical poetry, and only the full-grown man is capable of the drama. The old man we can think of as at the most an epic poet, like Ossian, and Homer, for narration is characteristic of old age.

In the more objective kinds of poetry, especially in the romance, the epic, and the drama, the end, the revelation of the Idea of man, is principally attained by two means, by true and profound representation of significant characters, and by the invention of pregnant situations in which they disclose themselves. For as it is incumbent upon the chemist not only to exhibit the simple elements, pure and genuine, and their principal compounds, but also to expose them to the influence of such reagents as will clearly and strikingly bring out their peculiar qualities, so is it incumbent on the poet not only to present to us significant characters truly and faithfully as nature itself; but, in order that we may get to know them, he must place them in those situations in which their peculiar qualities will fully unfold themselves, and appear distinctly in sharp outline; situations which are therefore called significant. In real life, and in history, situations of this kind are rarely brought about by chance, and they stand alone, lost

and concealed in the multitude of those which are insignificant. The complete significance of the situations ought to distinguish the romance, the epic, and the drama from real life as completely as the arrangement and selection of significant characters. In both, however, absolute truth is a necessary condition of their effect, and want of unity in the characters, contradiction either of themselves or of the nature of humanity in general, as well as impossibility, or very great improbability in the events, even in mere accessories, offend just as much in poetry as badly drawn figures, false perspective, or wrong lighting in painting. For both in poetry and painting we demand the faithful mirror of life, of man, of the world, only made more clear by the representation, and more significant by the arrangement. For there is only one end of all the arts, the representation of the Ideas; and their essential difference lies simply in the different grades of the objectification of will to which the Ideas that are to be represented belong. This also determines the material of the representation. Thus the arts which are most widely separated may yet throw light on each other. For example, in order to comprehend fully the Ideas of water it is not sufficient to see it in the quiet pond or in the evenly-flowing stream; but these Ideas disclose themselves fully only when the water appears under all circumstances and exposed to all kinds of obstacles. The effects of the varied circumstances and obstacles give it the opportunity of fully exhibiting all its qualities. This is why we find it beautiful when it tumbles, rushes, and foams, or leaps into the air, or falls in a cataract of spray; or, lastly, if artificially confined it springs up in a fountain. Thus showing itself different under different circumstances, it yet always faithfully asserts its character; it is just as natural to it to spout up as to lie in glassy stillness; it is as ready for the one as for the other as soon as the circumstances appear. Now, what the engineer achieves with the fluid matter of water, the architect achieves with the rigid matter of stone, and just this the epic or dramatic poet achieves with the Idea of man. Unfolding and rendering distinct the Idea expressing itself in the object of every art, the Idea of the will which objectifies itself at each grade, is the common end of all the arts. The life of man, as it shows itself for the most part in the real world, is like the water, as it is generally seen in the pond and the river; but in the epic, the romance, the tragedy, selected characters are placed in those circumstances in which all their special qualities unfold themselves, the depths of the human heart are revealed, and become visible in extraordinary and very significant

actions. Thus poetry objectifies the Idea of man, an Idea which has the peculiarity of expressing itself in highly individual characters.

Tragedy is to be regarded, and is recognised as the summit of poetical art, both on account of the greatness of its effect and the difficulty of its achievement. It is very significant for our whole system, and well worthy of observation, that the end of this highest poetical achievement is the representation of the terrible side of life. The unspeakable pain, the wail of humanity, the triumph of evil, the scornful mastery of chance, and the irretrievable fall of the just and innocent, is here presented to us; and in this lies a significant hint of the nature of the world and of existence. It is the strife of will with itself, which here, completely unfolded at the highest grade of its objectivity, comes into fearful prominence. It becomes visible in the suffering of men, which is now introduced, partly through chance and error, which appear as the rulers of the world, personified as fate, on account of their insidiousness, which even reaches the appearance of design; partly it proceeds from man himself, through the self-mortifying efforts of a few, through the wickedness and perversity of most. It is one and the same will that lives and appears in them all, but whose phenomena fight against each other and destroy each other. In one individual it appears powerfully, in another more weakly; in one more subject to reason, and softened by the light of knowledge, in another less so, till at last, in some single case, this knowledge, purified and heightened by suffering itself, reaches the point at which the phenomenon, the veil of Mâya, no longer deceives it. It sees through the form of the phenomenon, the *principium individuationis*. The egoism which rests on this perishes with it, so that now the *motives* that were so powerful before have lost their might, and instead of them the complete knowledge of the nature of the world, which has a *quieting* effect on the will, produces resignation, the surrender not merely of life, but of the very will to live. Thus we see in tragedies the noblest men, after long conflict and suffering, at last renounce the ends they have so keenly followed, and all the pleasures of life for ever, or else freely and joyfully surrender life itself. So is it with the steadfast prince of Calderon; with Gretchen in "Faust;" with Hamlet, whom his friend Horatio would willingly follow, but is bade remain a while, and in this harsh world draw his breath in pain, to tell the story of Hamlet, and clear his memory; so also is it with the Maid of Orleans, the Bride of Messina; they all die purified by suffering, *i.e.*, after the will to live which was formerly in them is dead. In

the “Mohammed” of Voltaire this is actually expressed in the concluding words which the dying Palmira addresses to Mohammad: “The world is for tyrants: live!” On the other hand, the demand for so-called poetical justice rests on entire misconception of the nature of tragedy, and, indeed, of the nature of the world itself. It boldly appears in all its dulness in the criticisms which Dr. Samuel Johnson made on particular plays of Shakespeare, for he very naïvely laments its entire absence. And its absence is certainly obvious, for in what has Ophelia, Desdemona, or Cordelia offended? But only the dull, optimistic, Protestant-rationalistic, or peculiarly Jewish view of life will make the demand for poetical justice, and find satisfaction in it. The true sense of tragedy is the deeper insight, that it is not his own individual sins that the hero atones for, but original sin, *i.e.*, the crime of existence itself:

“Pues el delito mayor
Del hombre es haber nacido;”
(“For the greatest crime of man
Is that he was born;”)
as Calderon exactly expresses it.

I shall allow myself only one remark, more closely concerning the treatment of tragedy. The representation of a great misfortune is alone essential to tragedy. But the many different ways in which this is introduced by the poet may be brought under three specific conceptions. It may happen by means of a character of extraordinary wickedness, touching the utmost limits of possibility, who becomes the author of the misfortune; examples of this kind are Richard III., Iago in “Othello,” Shylock in “The Merchant of Venice,” Franz Moor, Phædra of Euripides, Creon in the “Antigone,” &c., &c. Secondly, it may happen through blind fate, *i.e.*, chance and error; a true pattern of this kind is the Œdipus Rex of Sophocles, the “Trachiniæ” also; and in general most of the tragedies of the ancients belong to this class. Among modern tragedies, “Romeo and Juliet,” “Tancred” by Voltaire, and “The Bride of Messina,” are examples. Lastly, the misfortune may be brought about by the mere position of the *dramatis personæ* with regard to each other, through their relations; so that there is no need either for a tremendous error or an unheard-of accident, nor yet for a character whose wickedness reaches the limits of human possibility; but characters of ordinary morality, under circumstances such as often occur, are so situated with regard to each other that their position compels them, knowingly and

with their eyes open, to do each other the greatest injury, without any one of them being entirely in the wrong. This last kind of tragedy seems to me far to surpass the other two, for it shows us the greatest misfortune, not as an exception, not as something occasioned by rare circumstances or monstrous characters, but as arising easily and of itself out of the actions and characters of men, indeed almost as essential to them, and thus brings it terribly near to us. In the other two kinds we may look on the prodigious fate and the horrible wickedness as terrible powers which certainly threaten us, but only from afar, which we may very well escape without taking refuge in renunciation. But in the last kind of tragedy we see that those powers which destroy happiness and life are such that their path to us also is open at every moment; we see the greatest sufferings brought about by entanglements that our fate might also partake of, and through actions that perhaps we also are capable of performing, and so could not complain of injustice; then shuddering we feel ourselves already in the midst of hell. This last kind of tragedy is also the most difficult of achievement; for the greatest effect has to be produced in it with the least use of means and causes of movement, merely through the position and distribution of the characters; therefore even in many of the best tragedies this difficulty is evaded. Yet one tragedy may be referred to as a perfect model of this kind, a tragedy which in other respects is far surpassed by more than one work of the same great master; it is “Clavigo.” “Hamlet” belongs to a certain extent to this class, as far as the relation of Hamlet to Laertes and Ophelia is concerned. “Wallenstein” has also this excellence. “Faust” belongs entirely to this class, if we regard the events connected with Gretchen and her brother as the principal action; also the “Cid” of Corneille, only that it lacks the tragic conclusion, while on the contrary the analogous relation of Max to Thecla has it.[61]

§ 52. Now that we have considered all the fine arts in the general way that is suitable to our point of view, beginning with architecture, the peculiar end of which is to elucidate the objectification of will at the lowest grades of its visibility, in which it shows itself as the dumb unconscious tendency of the mass in accordance with laws, and yet already reveals a breach of the unity of will with itself in a conflict between gravity and rigidity — and ending with the consideration of tragedy, which presents to us at the highest grades of the objectification of will this very conflict with itself in terrible magnitude and distinctness; we find that there is still

another fine art which has been excluded from our consideration, and had to be excluded, for in the systematic connection of our exposition there was no fitting place for it — I mean *music*. It stands alone, quite cut off from all the other arts. In it we do not recognise the copy or repetition of any Idea of existence in the world. Yet it is such a great and exceedingly noble art, its effect on the inmost nature of man is so powerful, and it is so entirely and deeply understood by him in his inmost consciousness as a perfectly universal language, the distinctness of which surpasses even that of the perceptible world itself, that we certainly have more to look for in it than an *exercitum arithmeticæ occultum nescientis se numerare animi*,[62] which Leibnitz called it. Yet he was perfectly right, as he considered only its immediate external significance, its form. But if it were nothing more, the satisfaction which it affords would be like that which we feel when a sum in arithmetic comes out right, and could not be that intense pleasure with which we see the deepest recesses of our nature find utterance. From our standpoint, therefore, at which the æsthetic effect is the criterion, we must attribute to music a far more serious and deep significance, connected with the inmost nature of the world and our own self, and in reference to which the arithmetical proportions, to which it may be reduced, are related, not as the thing signified, but merely as the sign. That in some sense music must be related to the world as the representation to the thing represented, as the copy to the original, we may conclude from the analogy of the other arts, all of which possess this character, and affect us on the whole in the same way as it does, only that the effect of music is stronger, quicker, more necessary and infallible. Further, its representative relation to the world must be very deep, absolutely true, and strikingly accurate, because it is instantly understood by every one, and has the appearance of a certain infallibility, because its form may be reduced to perfectly definite rules expressed in numbers, from which it cannot free itself without entirely ceasing to be music. Yet the point of comparison between music and the world, the respect in which it stands to the world in the relation of a copy or repetition, is very obscure. Men have practised music in all ages without being able to account for this; content to understand it directly, they renounce all claim to an abstract conception of this direct understanding itself.

I gave my mind entirely up to the impression of music in all its forms, and then returned to reflection and the system of thought expressed in the present work, and thus I arrived at an explanation of the inner nature of

music and of the nature of its imitative relation to the world — which from analogy had necessarily to be presupposed — an explanation which is quite sufficient for myself, and satisfactory to my investigation, and which will doubtless be equally evident to any one who has followed me thus far and has agreed with my view of the world. Yet I recognise the fact that it is essentially impossible to prove this explanation, for it assumes and establishes a relation of music, as idea, to that which from its nature can never be idea, and music will have to be regarded as the copy of an original which can never itself be directly presented as idea. I can therefore do no more than state here, at the conclusion of this third book, which has been principally devoted to the consideration of the arts, the explanation of the marvellous art of music which satisfies myself, and I must leave the acceptance or denial of my view to the effect produced upon each of my readers both by music itself and by the whole system of thought communicated in this work. Moreover, I regard it as necessary, in order to be able to assent with full conviction to the exposition of the significance of music I am about to give, that one should often listen to music with constant reflection upon my theory concerning it, and for this again it is necessary to be very familiar with the whole of my system of thought.

The (Platonic) Ideas are the adequate objectification of will. To excite or suggest the knowledge of these by means of the representation of particular things (for works of art themselves are always representations of particular things) is the end of all the other arts, which can only be attained by a corresponding change in the knowing subject. Thus all these arts objectify the will indirectly only by means of the Ideas; and since our world is nothing but the manifestation of the Ideas in multiplicity, though their entrance into the *principium individuationis* (the form of the knowledge possible for the individual as such), music also, since it passes over the Ideas, is entirely independent of the phenomenal world, ignores it altogether, could to a certain extent exist if there was no world at all, which cannot be said of the other arts. Music is as *direct* an objectification and copy of the whole *will* as the world itself, nay, even as the Ideas, whose multiplied manifestation constitutes the world of individual things. Music is thus by no means like the other arts, the copy of the Ideas, but the *copy of the will itself*, whose objectivity the Ideas are. This is why the effect of music is so much more powerful and penetrating than that of the other arts, for they speak only of shadows, but it speaks of the thing itself. Since, however, it is the same will which objectifies itself both in the Ideas and in music, though in quite different ways, there must be, not indeed a direct likeness, but yet a parallel, an analogy, between music and the Ideas whose manifestation in multiplicity and incompleteness is the visible world. The establishing of this analogy will facilitate, as an illustration, the understanding of this exposition, which is so difficult on account of the obscurity of the subject.

I recognise in the deepest tones of harmony, in the bass, the lowest grades of the objectification of will, unorganised nature, the mass of the planet. It is well known that all the high notes which are easily sounded, and die away more quickly, are produced by the vibration in their vicinity of the deep bass-notes. When, also, the low notes sound, the high notes always sound faintly, and it is a law of harmony that only those high notes may accompany a bass-note which actually already sound along with it of themselves (its *sons harmoniques*) on account of its vibration. This is analogous to the fact that the whole of the bodies and organisations of nature must be regarded as having come into existence through gradual development out of the mass of the planet; this is both their supporter and their source, and the same relation subsists between the high notes and the

bass. There is a limit of depth, below which no sound is audible. This corresponds to the fact that no matter can be perceived without form and quality, *i.e.*, without the manifestation of a force which cannot be further explained, in which an Idea expresses itself, and, more generally, that no matter can be entirely without will. Thus, as a certain pitch is inseparable from the note as such, so a certain grade of the manifestation of will is inseparable from matter. Bass is thus, for us, in harmony what unorganised nature, the crudest mass, upon which all rests, and from which everything originates and develops, is in the world. Now, further, in the whole of the complemental parts which make up the harmony between the bass and the leading voice singing the melody, I recognise the whole gradation of the Ideas in which the will objectifies itself. Those nearer to the bass are the lower of these grades, the still unorganised, but yet manifold phenomenal things; the higher represent to me the world of plants and beasts. The definite intervals of the scale are parallel to the definite grades of the objectification of will, the definite species in nature. The departure from the arithmetical correctness of the intervals, through some temperament, or produced by the key selected, is analogous to the departure of the individual from the type of the species. Indeed, even the impure discords, which give no definite interval, may be compared to the monstrous abortions produced by beasts of two species, or by man and beast. But to all these bass and complemental parts which make up the *harmony* there is wanting that connected progress which belongs only to the high voice singing the melody, and it alone moves quickly and lightly in modulations and runs, while all these others have only a slower movement without a connection in each part for itself. The deep bass moves most slowly, the representative of the crudest mass. Its rising and falling occurs only by large intervals, in thirds, fourths, fifths, never by *one* tone, unless it is a base inverted by double counterpoint. This slow movement is also physically essential to it; a quick run or shake in the low notes cannot even be imagined. The higher complemental parts, which are parallel to animal life, move more quickly, but yet without melodious connection and significant progress. The disconnected course of all the complemental parts, and their regulation by definite laws, is analogous to the fact that in the whole irrational world, from the crystal to the most perfect animal, no being has a connected consciousness of its own which would make its life into a significant whole, and none experiences a succession of mental developments, none perfects

itself by culture, but everything exists always in the same way according to its kind, determined by fixed law. Lastly, in the *melody*, in the high, singing, principal voice leading the whole and progressing with unrestrained freedom, in the unbroken significant connection of *one* thought from beginning to end representing a whole, I recognise the highest grade of the objectification of will, the intellectual life and effort of man. As he alone, because endowed with reason, constantly looks before and after on the path of his actual life and its innumerable possibilities, and so achieves a course of life which is intellectual, and therefore connected as a whole; corresponding to this, I say, the *melody* has significant intentional connection from beginning to end. It records, therefore, the history of the intellectually enlightened will. This will expresses itself in the actual world as the series of its deeds; but melody says more, it records the most secret history of this intellectually-enlightened will, pictures every excitement, every effort, every movement of it, all that which the reason collects under the wide and negative concept of feeling, and which it cannot apprehend further through its abstract concepts. Therefore it has always been said that music is the language of feeling and of passion, as words are the language of reason. Plato explains it as ἡ των μελων κινησις μεμιμημενη, εν τοις παθημασιν ὁταν ψυχη γινηται (*melodiarum motus, animi affectus imitans*), De Leg. vii.; and also Aristotle says: δια τι οἱ ρυθμοι και τα μελη, φωνη ουσα, ηθεσιν εοικε (*cur numeri musici et modi, qui voces sunt, moribus similes sese exhibent?*): Probl. c. 19.

Now the nature of man consists in this, that his will strives, is satisfied and strives anew, and so on for ever. Indeed, his happiness and well-being consist simply in the quick transition from wish to satisfaction, and from satisfaction to a new wish. For the absence of satisfaction is suffering, the empty longing for a new wish, languor, *ennui*. And corresponding to this the nature of melody is a constant digression and deviation from the key-note in a thousand ways, not only to the harmonious intervals to the third and dominant, but to every tone, to the dissonant sevenths and to the superfluous degrees; yet there always follows a constant return to the key-note. In all these deviations melody expresses the multifarious efforts of will, but always its satisfaction also by the final return to an harmonious interval, and still more, to the key-note. The composition of melody, the disclosure in it of all the deepest secrets of human willing and feeling, is the work of genius, whose action, which is more apparent here than anywhere

else, lies far from all reflection and conscious intention, and may be called an inspiration. The conception is here, as everywhere in art, unfruitful. The composer reveals the inner nature of the world, and expresses the deepest wisdom in a language which his reason does not understand; as a person under the influence of mesmerism tells things of which he has no conception when he awakes. Therefore in the composer, more than in any other artist, the man is entirely separated and distinct from the artist. Even in the explanation of this wonderful art, the concept shows its poverty and limitation. I shall try, however, to complete our analogy. As quick transition from wish to satisfaction, and from satisfaction to a new wish, is happiness and well-being, so quick melodies without great deviations are cheerful; slow melodies, striking painful discords, and only winding back through many bars to the keynote are, as analogous to the delayed and hardly won satisfaction, sad. The delay of the new excitement of will, languor, could have no other expression than the sustained keynote, the effect of which would soon be unbearable; very monotonous and unmeaning melodies approach this effect. The short intelligible subjects of quick dance-music seem to speak only of easily attained common pleasure. On the other hand, the *Allegro maestoso*, in elaborate movements, long passages, and wide deviations, signifies a greater, nobler effort towards a more distant end, and its final attainment. The *Adagio* speaks of the pain of a great and noble effort which despises all trifling happiness. But how wonderful is the effect of the *minor* and *major*! How astounding that the change of half a tone, the entrance of a minor third instead of a major, at once and inevitably forces upon us an anxious painful feeling, from which again we are just as instantaneously delivered by the major. The *Adagio* lengthens in the minor the expression of the keenest pain, and becomes even a convulsive wail. Dance-music in the minor seems to indicate the failure of that trifling happiness which we ought rather to despise, seems to speak of the attainment of a lower end with toil and trouble. The inexhaustibleness of possible melodies corresponds to the inexhaustibleness of Nature in difference of individuals, physiognomies, and courses of life. The transition from one key to an entirely different one, since it altogether breaks the connection with what went before, is like death, for the individual ends in it; but the will which appeared in this individual lives after him as before him, appearing in other individuals, whose consciousness, however, has no connection with his.

But it must never be forgotten, in the investigation of all these analogies I have pointed out, that music has no direct, but merely an indirect relation to them, for it never expresses the phenomenon, but only the inner nature, the in-itself of all phenomena, the will itself. It does not therefore express this or that particular and definite joy, this or that sorrow, or pain, or horror, or delight, or merriment, or peace of mind; but joy, sorrow, pain, horror, delight, merriment, peace of mind *themselves*, to a certain extent in the abstract, their essential nature, without accessories, and therefore without their motives. Yet we completely understand them in this extracted quintessence. Hence it arises that our imagination is so easily excited by music, and now seeks to give form to that invisible yet actively moved spirit-world which speaks to us directly, and clothe it with flesh and blood, *i.e.*, to embody it in an analogous example. This is the origin of the song with words, and finally of the opera, the text of which should therefore never forsake that subordinate position in order to make itself the chief thing and the music a mere means of expressing it, which is a great misconception and a piece of utter perversity; for music always expresses only the quintessence of life and its events, never these themselves, and therefore their differences do not always affect it. It is precisely this universality, which belongs exclusively to it, together with the greatest determinateness, that gives music the high worth which it has as the panacea for all our woes. Thus, if music is too closely united to the words, and tries to form itself according to the events, it is striving to speak a language which is not its own. No one has kept so free from this mistake as Rossini; therefore his music speaks *its own language* so distinctly and purely that it requires no words, and produces its full effect when rendered by instruments alone.

According to all this, we may regard the phenomenal world, or nature, and music as two different expressions of the same thing, which is therefore itself the only medium of their analogy, so that a knowledge of it is demanded in order to understand that analogy. Music, therefore, if regarded as an expression of the world, is in the highest degree a universal language, which is related indeed to the universality of concepts, much as they are related to the particular things. Its universality, however, is by no means that empty universality of abstraction, but quite of a different kind, and is united with thorough and distinct definiteness. In this respect it resembles

geometrical figures and numbers, which are the universal forms of all possible objects of experience and applicable to them all *a priori*, and yet are not abstract but perceptible and thoroughly determined. All possible efforts, excitements, and manifestations of will, all that goes on in the heart of man and that reason includes in the wide, negative concept of feeling, may be expressed by the infinite number of possible melodies, but always in the universal, in the mere form, without the material, always according to the thing-in-itself, not the phenomenon, the inmost soul, as it were, of the phenomenon, without the body. This deep relation which music has to the true nature of all things also explains the fact that suitable music played to any scene, action, event, or surrounding seems to disclose to us its most secret meaning, and appears as the most accurate and distinct commentary upon it. This is so truly the case, that whoever gives himself up entirely to the impression of a symphony, seems to see all the possible events of life and the world take place in himself, yet if he reflects, he can find no likeness between the music and the things that passed before his mind. For, as we have said, music is distinguished from all the other arts by the fact that it is not a copy of the phenomenon, or, more accurately, the adequate objectivity of will, but is the direct copy of the will itself, and therefore exhibits itself as the metaphysical to everything physical in the world, and as the thing-in-itself to every phenomenon. We might, therefore, just as well call the world embodied music as embodied will; and this is the reason why music makes every picture, and indeed every scene of real life and of the world, at once appear with higher significance, certainly all the more in proportion as its melody is analogous to the inner spirit of the given phenomenon. It rests upon this that we are able to set a poem to music as a song, or a perceptible representation as a pantomime, or both as an opera. Such particular pictures of human life, set to the universal language of music, are never bound to it or correspond to it with stringent necessity; but they stand to it only in the relation of an example chosen at will to a general concept. In the determinateness of the real, they represent that which music expresses in the universality of mere form. For melodies are to a certain extent, like general concepts, an abstraction from the actual. This actual world, then, the world of particular things, affords the object of perception, the special and individual, the particular case, both to the universality of the concepts and to the universality of the melodies. But these two universalities are in a certain respect opposed to each other; for the concepts

contain particulars only as the first forms abstracted from perception, as it were, the separated shell of things; thus they are, strictly speaking, *abstracta*; music, on the other hand, gives the inmost kernel which precedes all forms, or the heart of things. This relation may be very well expressed in the language of the schoolmen by saying the concepts are the *universalia post rem*, but music gives the *universalia ante rem*, and the real world the *universalia in re*. To the universal significance of a melody to which a poem has been set, it is quite possible to set other equally arbitrarily selected examples of the universal expressed in this poem corresponding to the significance of the melody in the same degree. This is why the same composition is suitable to many verses; and this is also what makes the *vaudeville* possible. But that in general a relation is possible between a composition and a perceptible representation rests, as we have said, upon the fact that both are simply different expressions of the same inner being of the world. When now, in the particular case, such a relation is actually given, that is to say, when the composer has been able to express in the universal language of music the emotions of will which constitute the heart of an event, then the melody of the song, the music of the opera, is expressive. But the analogy discovered by the composer between the two must have proceeded from the direct knowledge of the nature of the world unknown to his reason, and must not be an imitation produced with conscious intention by means of conceptions, otherwise the music does not express the inner nature of the will itself, but merely gives an inadequate imitation of its phenomenon. All specially imitative music does this; for example, "The Seasons," by Haydn; also many passages of his "Creation," in which phenomena of the external world are directly imitated; also all battle-pieces. Such music is entirely to be rejected.

The unutterable depth of all music by virtue of which it floats through our consciousness as the vision of a paradise firmly believed in yet ever distant from us, and by which also it is so fully understood and yet so inexplicable, rests on the fact that it restores to us all the emotions of our inmost nature, but entirely without reality and far removed from their pain. So also the seriousness which is essential to it, which excludes the absurd from its direct and peculiar province, is to be explained by the fact that its object is not the idea, with reference to which alone deception and absurdity are possible; but its object is directly the will, and this is essentially the most serious of all things, for it is that on which all depends. How rich in

content and full of significance the language of music is, we see from the repetitions, as well as the *Da capo*, the like of which would be unbearable in works composed in a language of words, but in music are very appropriate and beneficial, for, in order to comprehend it fully, we must hear it twice.

In the whole of this exposition of music I have been trying to bring out clearly that it expresses in a perfectly universal language, in a homogeneous material, mere tones, and with the greatest determinateness and truth, the inner nature, the in-itself of the world, which we think under the concept of will, because will is its most distinct manifestation. Further, according to my view and contention, philosophy is nothing but a complete and accurate repetition or expression of the nature of the world in very general concepts, for only in such is it possible to get a view of that whole nature which will everywhere be adequate and applicable. Thus, whoever has followed me and entered into my mode of thought, will not think it so very paradoxical if I say, that supposing it were possible to give a perfectly accurate, complete explanation of music, extending even to particulars, that is to say, a detailed repetition in concepts of what it expresses, this would also be a sufficient repetition and explanation of the world in concepts, or at least entirely parallel to such an explanation, and thus it would be the true philosophy. Consequently the saying of Leibnitz quoted above, which is quite accurate from a lower standpoint, may be parodied in the following way to suit our higher view of music: *Musica est exercitium metaphysices occultum nescientis se philosophari animi*; for *scire*, to know, always means to have fixed in abstract concepts. But further, on account of the truth of the saying of Leibnitz, which is confirmed in various ways, music, regarded apart from its æsthetic or inner significance, and looked at merely externally and purely empirically, is simply the means of comprehending directly and in the concrete large numbers and complex relations of numbers, which otherwise we could only know indirectly by fixing them in concepts. Therefore by the union of these two very different but correct views of music we may arrive at a conception of the possibility of a philosophy of number, such as that of Pythagoras and of the Chinese in Y-King, and then interpret in this sense the saying of the Pythagoreans which Sextus Empiricus quotes (adv. Math., L. vii.): τῳ αριθμῳ δε τα παντ᾽ επεοικεν (*numero cuncta assimilantur*). And if, finally, we apply this view to the interpretation of harmony and melody given above, we shall find that a

mere moral philosophy without an explanation of Nature, such as Socrates wanted to introduce, is precisely analogous to a mere melody without harmony, which Rousseau exclusively desired; and, in opposition to this mere physics and metaphysics without ethics, will correspond to mere harmony without melody. Allow me to add to these cursory observations a few more remarks concerning the analogy of music with the phenomenal world. We found in the second book that the highest grade of the objectification of will, man, could not appear alone and isolated, but presupposed the grades below him, as these again presupposed the grades lower still. In the same way music, which directly objectifies the will, just as the world does, is complete only in full harmony. In order to achieve its full effect, the high leading voice of the melody requires the accompaniment of all the other voices, even to the lowest bass, which is to be regarded as the origin of all. The melody itself enters as an integral part into the harmony, as the harmony enters into it, and only thus, in the full harmonious whole, music expresses what it aims at expressing. Thus also the one will outside of time finds its full objectification only in the complete union of all the steps which reveal its nature in the innumerable ascending grades of distinctness. The following analogy is also very remarkable. We have seen in the preceding book that notwithstanding the self-adaptation of all the phenomena of will to each other as regards their species, which constitutes their teleological aspect, there yet remains an unceasing conflict between those phenomena as individuals, which is visible at every grade, and makes the world a constant battle-field of all those manifestations of one and the same will, whose inner contradiction with itself becomes visible through it. In music also there is something corresponding to this. A complete, pure, harmonious system of tones is not only physically but arithmetically impossible. The numbers themselves by which the tones are expressed have inextricable irrationality. There is no scale in which, when it is counted, every fifth will be related to the keynote as 2 to 3, every major third as 4 to 5, every minor third as 5 to 6, and so on. For if they are correctly related to the keynote, they can no longer be so to each other; because, for example, the fifth must be the minor third to the third, &c. For the notes of the scale may be compared to actors who must play now one part, now another. Therefore a perfectly accurate system of music cannot even be thought, far less worked out; and on this account all possible music deviates from perfect purity; it can only conceal the discords essential to it

by dividing them among all the notes, *i.e.*, by temperament. On this see Chladni's "Akustik," § 30, and his "Kurze Uebersicht der Schall- und Klanglehre."[63]

I might still have something to say about the way in which music is perceived, namely, in and through time alone, with absolute exclusion of space, and also apart from the influence of the knowledge of causality, thus without understanding; for the tones make the æsthetic impression as effect, and without obliging us to go back to their causes, as in the case of perception. I do not wish, however, to lengthen this discussion, as I have perhaps already gone too much into detail with regard to some things in this Third Book, or have dwelt too much on particulars. But my aim made it necessary, and it will be the less disapproved if the importance and high worth of art, which is seldom sufficiently recognised, be kept in mind. For if, according to our view, the whole visible world is just the objectification, the mirror, of the will, conducting it to knowledge of itself, and, indeed, as we shall soon see, to the possibility of its deliverance; and if, at the same time, the world as idea, if we regard it in isolation, and, freeing ourselves from all volition, allow it alone to take possession of our consciousness, is the most joy-giving and the only innocent side of life; we must regard art as the higher ascent, the more complete development of all this, for it achieves essentially just what is achieved by the visible world itself, only with greater concentration, more perfectly, with intention and intelligence, and therefore may be called, in the full significance of the word, the flower of life. If the whole world as idea is only the visibility of will, the work of art is to render this visibility more distinct. It is the *camera obscura* which shows the objects more purely, and enables us to survey them and comprehend them better. It is the play within the play, the stage upon the stage in "Hamlet."

The pleasure we receive from all beauty, the consolation which art affords, the enthusiasm of the artist, which enables him to forget the cares of life, — the latter an advantage of the man of genius over other men, which alone repays him for the suffering that increases in proportion to the clearness of consciousness, and for the desert loneliness among men of a different race, — all this rests on the fact that the in-itself of life, the will, existence itself, is, as we shall see farther on, a constant sorrow, partly miserable, partly terrible; while, on the contrary, as idea alone, purely contemplated, or copied by art, free from pain, it presents to us a drama full

of significance. This purely knowable side of the world, and the copy of it in any art, is the element of the artist. He is chained to the contemplation of the play, the objectification of will; he remains beside it, does not get tired of contemplating it and representing it in copies; and meanwhile he bears himself the cost of the production of that play, *i.e.*, he himself is the will which objectifies itself, and remains in constant suffering. That pure, true, and deep knowledge of the inner nature of the world becomes now for him an end in itself: he stops there. Therefore it does not become to him a quieter of the will, as, we shall see in the next book, it does in the case of the saint who has attained to resignation; it does not deliver him for ever from life, but only at moments, and is therefore not for him a path out of life, but only an occasional consolation in it, till his power, increased by this contemplation and at last tired of the play, lays hold on the real. The St. Cecilia of Raphael may be regarded as a representation of this transition. To the real, then, we now turn in the following book.

Fourth Book. The World As Will.

Second Aspect. The Assertion And Denial Of The Will To Live, When Self-Consciousness Has Been Attained.

Tempore quo cognitio simul advenit, amor e medio supersurrexit. — *Oupnek'hat,*
Studio Anquetil Duperron, vol. ii. p. 216.

§ 53. The last part of our work presents itself as the most serious, for it relates to the action of men, the matter which concerns every one directly and can be foreign or indifferent to none. It is indeed so characteristic of the nature of man to relate everything else to action, that in every systematic investigation he will always treat the part that has to do with action as the result or outcome of the whole work, so far, at least, as it interests him, and will therefore give his most serious attention to this part, even if to no other. In this respect the following part of our work would, in ordinary language, be called practical philosophy, in opposition to the theoretical, which has occupied us hitherto. But, in my opinion, all philosophy is theoretical, because it is essential to it that it should retain a purely contemplative attitude, and should investigate, not prescribe. To become, on the contrary, practical, to guide conduct, to transform character, are old claims, which with fuller insight it ought finally to give up. For here, where the worth or worthlessness of an existence, where salvation or damnation are in question, the dead conceptions of philosophy do not decide the matter, but the inmost nature of man himself, the Dæmon that guides him and that has not chosen him, but been chosen by him, as Plato would say; his intelligible character, as Kant expresses himself. Virtue cannot be taught any more than genius; indeed, for it the concept is just as unfruitful as it is in art, and in both cases can only be used as an instrument. It would, therefore, be just as absurd to expect that our moral systems and ethics will produce virtuous, noble, and holy men, as that our æsthetics will produce poets, painters, and musicians.

Philosophy can never do more than interpret and explain what is given. It can only bring to distinct abstract knowledge of the reason the nature of the world which in the concrete, that is, as feeling, expresses itself comprehensibly to every one. This, however, it does in every possible reference and from every point of view. Now, as this attempt has been made from other points of view in the three preceding books with the generality that is proper to philosophy, in this book the action of men will be

considered in the same way; and this side of the world might, indeed, be considered the most important of all, not only subjectively, as I remarked above, but also objectively. In considering it I shall faithfully adhere to the method I have hitherto followed, and shall support myself by presupposing all that has already been advanced. There is, indeed, just one thought which forms the content of this whole work. I have endeavoured to work it out in all other spheres, and I shall now do so with regard to human action. I shall then have done all that is in my power to communicate it as fully as possible.

The given point of view, and the method of treatment announced, are themselves sufficient to indicate that in this ethical book no precepts, no doctrine of duty must be looked for; still less will a general moral principle be given, an universal receipt, as it were, for the production of all the virtues. Neither shall we talk of an "*absolute ought*," for this contains a contradiction, as is explained in the Appendix; nor yet of a "*law of freedom*," which is in the same position. In general, we shall not speak at all of "ought," for this is how one speaks to children and to nations still in their childhood, but not to those who have appropriated all the culture of a full-grown age. It is a palpable contradiction to call the will free, and yet to prescribe laws for it according to which it ought to will. "Ought to will!" — wooden iron! But it follows from the point of view of our system that the will is not only free, but almighty. From it proceeds not only its action, but also its world; and as the will is, so does its action and its world become. Both are the self-knowledge of the will and nothing more. The will determines itself, and at the same time both its action and its world; for besides it there is nothing, and these are the will itself. Only thus is the will truly autonomous, and from every other point of view it is heteronomous. Our philosophical endeavours can only extend to exhibiting and explaining the action of men in its inner nature and content, the various and even opposite maxims, whose living expression it is. This we shall do in connection with the preceding portion of our work, and in precisely the same way as we have hitherto explained the other phenomena of the world, and have sought to bring their inmost nature to distinct abstract knowledge. Our philosophy will maintain the same *immanency* in the case of action, as in all that we have hitherto considered. Notwithstanding Kant's great doctrine, it will not attempt to use the forms of the phenomenon, the universal expression of which is the principle of sufficient reason, as a

leaping-pole to jump over the phenomenon itself, which alone gives meaning to these forms, and land in the boundless sphere of empty fictions. But this actual world of experience, in which we are, and which is in us, remains both the material and the limits of our consideration: a world which is so rich in content that even the most searching investigation of which the human mind is capable could not exhaust it. Since then the real world of experience will never fail to afford material and reality to our ethical investigations, any more than to those we have already conducted, nothing will be less needful than to take refuge in negative conceptions void of content, and then somehow or other make even ourselves believe that we are saying something when we speak with lifted eyebrows of "absolutes," "infinites," "supersensibles," and whatever other mere negations of this sort there may be (ουδεν εστι, η το της στερησεως ονομα, μετα αμυδρας επινοιας — *nihil est, nisi negationis nomen, cum obscura notione*. — Jul. or. 5), instead of which it would be shorter to say at once cloud-cuckoo-town (νεφελοκοκκυγια): we shall not require to serve up covered empty dishes of this kind. Finally, we shall not in this book, any more than in those which have preceded it, narrate histories and give them out as philosophy. For we are of opinion that whoever supposes that the inner nature of the world can in any way, however plausibly disguised, be *historically* comprehended, is infinitely far from a philosophical knowledge of the world. Yet this is what is supposed whenever a "becoming," or a "having become," or an "about to become" enters into a theory of the nature of the world, whenever an earlier or a later has the least place in it; and in this way a beginning and an end of the world, and the path it pursues between them, is, either openly or disguisedly, both sought for and found, and the individual who philosophises even recognises his own position on that path. Such *historical philosophising* in most cases produces a cosmogony which admits of many varieties, or else a system of emanations, a doctrine of successive disengagements from one being; or, finally, driven in despair from fruitless efforts upon these paths to the last path of all, it takes refuge in the converse doctrine of a constant becoming, springing up, arising, coming to light out of darkness, out of the hidden ground source or groundlessness, or whatever other nonsense of this sort there may be, which is most shortly disposed of with the remark that at the present moment a whole eternity, *i.e.*, an endless time, has already passed, so that everything that can or ought to become must have already done so. For all such

historical philosophy, whatever airs it may give itself, regards *time* just as if Kant had never lived, as a quality of the thing-in-itself, and thus stops at that which Kant calls the phenomenon in opposition to the thing-in-itself; which Plato calls the becoming and never being, in opposition to the being and never becoming; and which, finally, is called in the Indian philosophy the web of Mâya. It is just the knowledge which belongs to the principle of sufficient reason, with which no one can penetrate to the inner nature of things, but endlessly pursues phenomena, moving without end or aim, like a squirrel in its wheel, till, tired out at last, he stops at some point or other arbitrarily chosen, and now desires to extort respect for it from others also. The genuine philosophical consideration of the world, *i.e.*, the consideration that affords us a knowledge of its inner nature, and so leads us beyond the phenomenon, is precisely that method which does not concern itself with the whence, the whither, and the why of the world, but always and everywhere demands only the what; the method which considers things not according to any relation, not as becoming and passing away, in short, not according to one of the four forms of the principle of sufficient reason; but, on the contrary, just that which remains when all that belongs to the form of knowledge proper to that principle has been abstracted, the inner nature of the world, which always appears unchanged in all the relations, but is itself never subject to them, and has the Ideas of the world as its object or material. From such knowledge as this proceeds philosophy, like art, and also, as we shall see in this book, that disposition of mind which alone leads to true holiness and to deliverance from the world.

§ 54. The first three books will, it is hoped, have conveyed the distinct and certain knowledge that the world as idea is the complete mirror of the will, in which it knows itself in ascending grades of distinctness and completeness, the highest of which is man, whose nature, however, receives its complete expression only through the whole connected series of his actions. The self-conscious connection of these actions is made possible by reason, which enables a man constantly to survey the whole in the abstract.

The will, which, considered purely in itself, is without knowledge, and is merely a blind incessant impulse, as we see it appear in unorganised and vegetable nature and their laws, and also in the vegetative part of our own life, receives through the addition of the world as idea, which is developed in subjection to it, the knowledge of its own willing and of what it is that it wills. And this is nothing else than the world as idea, life, precisely as it

exists. Therefore we called the phenomenal world the mirror of the will, its objectivity. And since what the will wills is always life, just because life is nothing but the representation of that willing for the idea, it is all one and a mere pleonism if, instead of simply saying "the will," we say "the will to live."

Will is the thing-in-itself, the inner content, the essence of the world. Life, the visible world, the phenomenon, is only the mirror of the will. Therefore life accompanies the will as inseparably as the shadow accompanies the body; and if will exists, so will life, the world, exist. Life is, therefore, assured to the will to live; and so long as we are filled with the will to live we need have no fear for our existence, even in the presence of death. It is true we see the individual come into being and pass away; but the individual is only phenomenal, exists only for the knowledge which is bound to the principle of sufficient reason, to the *principio individuationis*. Certainly, for this kind of knowledge, the individual receives his life as a gift, rises out of nothing, then suffers the loss of this gift through death, and returns again to nothing. But we desire to consider life philosophically, *i.e.*, according to its Ideas, and in this sphere we shall find that neither the will, the thing-in-itself in all phenomena, nor the subject of knowing, that which perceives all phenomena, is affected at all by birth or by death. Birth and death belong merely to the phenomenon of will, thus to life; and it is essential to this to exhibit itself in individuals which come into being and pass away, as fleeting phenomena appearing in the form of time — phenomena of that which in itself knows no time, but must exhibit itself precisely in the way we have said, in order to objectify its peculiar nature. Birth and death belong in like manner to life, and hold the balance as reciprocal conditions of each other, or, if one likes the expression, as poles of the whole phenomenon of life. The wisest of all mythologies, the Indian, expresses this by giving to the very god that symbolises destruction, death (as Brahma, the most sinful and the lowest god of the Trimurti, symbolises generation, coming into being, and Vishnu maintaining or preserving), by giving, I say, to Siva as an attribute not only the necklace of skulls, but also the lingam, the symbol of generation, which appears here as the counterpart of death, thus signifying that generation and death are essentially correlatives, which reciprocally neutralise and annul each other. It was precisely the same sentiment that led the Greeks and Romans to adorn their costly sarcophagi, just as we see them now, with feasts, dances, marriages,

the chase, fights of wild beasts, bacchanalians, &c.; thus with representations of the full ardour of life, which they place before us not only in such revels and sports, but also in sensual groups, and even go so far as to represent the sexual intercourse of satyrs and goats. Clearly the aim was to point in the most impressive manner away from the death of the mourned individual to the immortal life of nature, and thus to indicate, though without abstract knowledge, that the whole of nature is the phenomenon and also the fulfilment of the will to live. The form of this phenomenon is time, space, and causality, and by means of these individuation, which carries with it that the individual must come into being and pass away. But this no more affects the will to live, of whose manifestation the individual is, as it were, only a particular example or specimen, than the death of an individual injures the whole of nature. For it is not the individual, but only the species that Nature cares for, and for the preservation of which she so earnestly strives, providing for it with the utmost prodigality through the vast surplus of the seed and the great strength of the fructifying impulse. The individual, on the contrary, neither has nor can have any value for Nature, for her kingdom is infinite time and infinite space, and in these infinite multiplicity of possible individuals. Therefore she is always ready to let the individual fall, and hence it is not only exposed to destruction in a thousand ways by the most insignificant accident, but originally destined for it, and conducted towards it by Nature herself from the moment it has served its end of maintaining the species. Thus Nature naïvely expresses the great truth that only the Ideas, not the individuals, have, properly speaking, reality, *i.e.*, are complete objectivity of the will. Now, since man is Nature itself, and indeed Nature at the highest grade of its self-consciousness, but Nature is only the objectified will to live, the man who has comprehended and retained this point of view may well console himself, when contemplating his own death and that of his friends, by turning his eyes to the immortal life of Nature, which he himself is. This is the significance of Siva with the lingam, and of those ancient sarcophagi with their pictures of glowing life, which say to the mourning beholder, *Natura non contristatur*.

That generation and death are to be regarded as something belonging to life, and essential to this phenomenon of the will, arises also from the fact that they both exhibit themselves merely as higher powers of the expression of that in which all the rest of life consists. This is through and through nothing else than the constant change of matter in the fixed

permanence of form; and this is what constitutes the transitoriness of the individual and the permanence of the species. Constant nourishment and renewal differ from generation only in degree, and constant excretion differs only in degree from death. The first shows itself most simply and distinctly in the plant. The plant is throughout a constant recurrence of the same impulse of its simplest fibre, which groups itself into leaf and branch. It is a systematic aggregate of similar plants supporting each other, whose constant reproduction is its single impulse. It ascends to the full satisfaction of this tendency through the grades of its metamorphosis, finally to the blossom and fruit, that compendium of its existence and effort in which it now attains, by a short way, to that which is its single aim, and at a stroke produces a thousand-fold what, up till then, it effected only in the particular case — the repetition of itself. Its earlier growth and development stands in the same relation to its fruit as writing stands to printing. With the animal it is clearly quite the same. The process of nourishing is a constant reproduction; the process of reproduction is a higher power of nourishing. The pleasure which accompanies the act of procreation is a higher power of the agreeableness of the sense of life. On the other hand, excretion, the constant exhalation and throwing off of matter, is the same as that which, at a higher power, death, is the contrary of generation. And if here we are always content to retain the form without lamenting the discarded matter, we ought to bear ourselves in the same way if in death the same thing happens, in a higher degree and to the whole, as takes place daily and hourly in a partial manner in excretion: if we are indifferent to the one, we ought not to shrink from the other. Therefore, from this point of view, it appears just as perverse to desire the continuance of an individuality which will be replaced by other individuals as to desire the permanence of matter which will be replaced by other matter. It appears just as foolish to embalm the body as it would be carefully to preserve its excrement. As to the individual consciousness which is bound to the individual body, it is absolutely interrupted every day by sleep. Deep sleep is, while it lasts, in no way different from death, into which, in fact, it often passes continuously, as in the case of freezing to death. It differs only with regard to the future, the awaking. Death is a sleep in which individuality is forgotten; everything else wakes again, or rather never slept.[64]

Above all things, we must distinctly recognise that the form of the phenomenon of will, the form of life or reality, is really only the *present*,

not the future nor the past. The latter are only in the conception, exist only in the connection of knowledge, so far as it follows the principle of sufficient reason. No man has ever lived in the past, and none will live in the future; the *present* alone is the form of all life, and is its sure possession which can never be taken from it. The present always exists, together with its content. Both remain fixed without wavering, like the rainbow on the waterfall. For life is firm and certain in the will, and the present is firm and certain in life. Certainly, if we reflect on the thousands of years that are past, of the millions of men who lived in them, we ask, What were they? what has become of them? But, on the other hand, we need only recall our own past life and renew its scenes vividly in our imagination, and then ask again, What was all this? what has become of it? As it is with it, so is it with the life of those millions. Or should we suppose that the past could receive a new existence because it has been sealed by death? Our own past, the most recent part of it, and even yesterday, is now no more than an empty dream of the fancy, and such is the past of all those millions. What was? What is? The will, of which life is the mirror, and knowledge free from will, which beholds it clearly in that mirror. Whoever has not yet recognised this, or will not recognise it, must add to the question asked above as to the fate of past generations of men this question also: Why he, the questioner, is so fortunate as to be conscious of this costly, fleeting, and only real present, while those hundreds of generations of men, even the heroes and philosophers of those ages, have sunk into the night of the past, and have thus become nothing; but he, his insignificant ego, actually exists? or more shortly, though somewhat strangely: Why this now, his now, *is* just now and *was* not long ago? Since he asks such strange questions, he regards his existence and his time as independent of each other, and the former as projected into the latter. He assumes indeed two nows — one which belongs to the object, the other which belongs to the subject, and marvels at the happy accident of their coincidence. But in truth, only the point of contact of the object, the form of which is time, with the subject, which has no mode of the principle of sufficient reason as its form, constitutes the present, as is shown in the essay on the principle of sufficient reason. Now all object is the will so far as it has become idea, and the subject is the necessary correlative of the object. But real objects are only in the present; the past and the future contain only conceptions and fancies, therefore the present is the essential form of the phenomenon of the will, and inseparable

from it. The present alone is that which always exists and remains immovable. That which, empirically apprehended, is the most transitory of all, presents itself to the metaphysical vision, which sees beyond the forms of empirical perception, as that which alone endures, the *nunc stans* of the schoolmen. The source and the supporter of its content is the will to live or the thing-in-itself, — which we are. That which constantly becomes and passes away, in that it has either already been or is still to be, belongs to the phenomenon as such on account of its forms, which make coming into being and passing away possible. Accordingly, we must think: — *Quid fuit?* — *Quod est. Quid erit?* — *Quod fuit;* and take it in the strict meaning of the words; thus understand not *simile* but *idem*. For life is certain to the will, and the present is certain to life. Thus it is that every one can say, "I am once for all lord of the present, and through all eternity it will accompany me as my shadow: therefore I do not wonder where it has come from, and how it happens that it is exactly now." We might compare time to a constantly revolving sphere; the half that was always sinking would be the past, that which was always rising would be the future; but the indivisible point at the top, where the tangent touches, would be the extensionless present. As the tangent does not revolve with the sphere, neither does the present, the point of contact of the object, the form of which is time, with the subject, which has no form, because it does not belong to the knowable, but is the condition of all that is knowable. Or, time is like an unceasing stream, and the present a rock on which the stream breaks itself, but does not carry away with it. The will, as thing-in-itself, is just as little subordinate to the principle of sufficient reason as the subject of knowledge, which, finally, in a certain regard is the will itself or its expression. And as life, its own phenomenon, is assured to the will, so is the present, the single form of real life. Therefore we have not to investigate the past before life, nor the future after death: we have rather to know the *present*, the one form in which the will manifests itself.[65] It will not escape from the will, but neither will the will escape from it. If, therefore, life as it is satisfies, whoever affirms it in every way may regard it with confidence as endless, and banish the fear of death as an illusion that inspires him with the foolish dread that he can ever be robbed of the present, and foreshadows a time in which there is no present; an illusion with regard to time analogous to the illusion with regard to space through which every one imagines the position on the globe he happens to occupy as above, and all

other places as below. In the same way every one links the present to his own individuality, and imagines that all present is extinguished with it; that then past and future might be without a present. But as on the surface of the globe every place is above, so the form of all life is the *present*, and to fear death because it robs us of the present, is just as foolish as to fear that we may slip down from the round globe upon which we have now the good fortune to occupy the upper surface. The present is the form essential to the objectification of the will. It cuts time, which extends infinitely in both directions, as a mathematical point, and stands immovably fixed, like an everlasting mid-day with no cool evening, as the actual sun burns without intermission, while it only seems to sink into the bosom of night. Therefore, if a man fears death as his annihilation, it is just as if he were to think that the sun cries out at evening, "Woe is me! for I go down into eternal night."[66] And conversely, whoever is oppressed with the burden of life, whoever desires life and affirms it, but abhors its torments, and especially can no longer endure the hard lot that has fallen to himself, such a man has no deliverance to hope for from death, and cannot right himself by suicide. The cool shades of Orcus allure him only with the false appearance of a haven of rest. The earth rolls from day into night, the individual dies, but the sun itself shines without intermission, an eternal noon. Life is assured to the will to live; the form of life is an endless present, no matter how the individuals, the phenomena of the Idea, arise and pass away in time, like fleeting dreams. Thus even already suicide appears to us as a vain and therefore a foolish action; when we have carried our investigation further it will appear to us in a still less favourable light.

Dogmas change and our knowledge is deceptive; but Nature never errs, her procedure is sure, and she never conceals it. Everything is entirely in Nature, and Nature is entire in everything. She has her centre in every brute. It has surely found its way into existence, and it will surely find its way out of it. In the meantime it lives, fearless and without care, in the presence of annihilation, supported by the consciousness that it is Nature herself, and imperishable as she is. Man alone carries about with him, in abstract conceptions, the certainty of his death; yet this can only trouble him very rarely, when for a single moment some occasion calls it up to his imagination. Against the mighty voice of Nature reflection can do little. In man, as in the brute which does not think, the certainty that springs from his inmost consciousness that he himself is Nature, the world, predominates as

a lasting frame of mind; and on account of this no man is observably disturbed by the thought of certain and never-distant death, but lives as if he would live for ever. Indeed this is carried so far that we may say that no one has really a lively conviction of the certainty of his death, otherwise there would be no great difference between his frame of mind and that of a condemned criminal. Every one recognises that certainty in the abstract and theoretically, but lays it aside like other theoretical truths which are not applicable to practice, without really receiving it into his living consciousness. Whoever carefully considers this peculiarity of human character will see that the psychological explanations of it, from habit and acquiescence in the inevitable, are by no means sufficient, and that its true explanation lies in the deeper ground we have given. The same fact explains the circumstance that at all times and among all peoples dogmas of some kind or other relating to the continued existence of the individual after death arise, and are believed in, although the evidence in support of them must always be very insufficient, and the evidence against them forcible and varied. But, in truth, this really requires no proof, but is recognised by the healthy understanding as a fact, and confirmed by the confidence that Nature never lies any more than she errs, but openly exhibits and naïvely expresses her action and her nature, while only we ourselves obscure it by our folly, in order to establish what is agreeable to our limited point of view.

But this that we have brought to clearest consciousness, that although the particular phenomenon of the will has a temporal beginning and end, the will itself as thing-in-itself is not affected by it, nor yet the correlative of all object, the knowing but never known subject, and that life is always assured to the will to live — this is not to be numbered with the doctrines of immortality. For permanence has no more to do with the will or with the pure subject of knowing, the eternal eye of the world, than transitoriness, for both are predicates that are only valid in time, and the will and the pure subject of knowing lie outside time. Therefore the egoism of the individual (this particular phenomenon of will enlightened by the subject of knowing) can extract as little nourishment and consolation for his wish to endure through endless time from the view we have expressed, as he could from the knowledge that after his death the rest of the eternal world would continue to exist, which is just the expression of the same view considered objectively, and therefore temporally. For every individual is transitory only as phenomenon, but as thing-in-itself is timeless, and therefore endless. But

it is also only as phenomenon that an individual is distinguished from the other things of the world; as thing-in-itself he is the will which appears in all, and death destroys the illusion which separates his consciousness from that of the rest: this is immortality. His exemption from death, which belongs to him only as thing-in-itself, is for the phenomenon one with the immortality of the rest of the external world.[67] Hence also, it arises that although the inward and merely felt consciousness of that which we have raised to distinct knowledge is indeed, as we have said, sufficient to prevent the thought of death from poisoning the life of the rational being, because this consciousness is the basis of that love of life which maintains everything living, and enables it to live on at ease as if there were no such thing as death, so long as it is face to face with life, and turns its attention to it, yet it will not prevent the individual from being seized with the fear of death, and trying in every way to escape from it, when it presents itself to him in some particular real case, or even only in his imagination, and he is compelled to contemplate it. For just as, so long as his knowledge was directed to life as such, he was obliged to recognise immortality in it, so when death is brought before his eyes, he is obliged to recognise it as that which it is, the temporal end of the particular temporal phenomenon. What we fear in death is by no means the pain, for it lies clearly on this side of death, and, moreover, we often take refuge in death from pain, just as, on the contrary, we sometimes endure the most fearful suffering merely to escape death for a while, although it would be quick and easy. Thus we distinguish pain and death as two entirely different evils. What we fear in death is the end of the individual, which it openly professes itself to be, and since the individual is a particular objectification of the will to live itself, its whole nature struggles against death. Now when feeling thus exposes us helpless, reason can yet step in and for the most part overcome its adverse influence, for it places us upon a higher standpoint, from which we no longer contemplate the particular but the whole. Therefore a philosophical knowledge of the nature of the world, which extended to the point we have now reached in this work but went no farther, could even at this point of view overcome the terror of death in the measure in which reflection had power over direct feeling in the given individual. A man who had thoroughly assimilated the truths we have already advanced, but had not come to know, either from his own experience or from a deeper insight, that constant suffering is essential to life, who found satisfaction and all that he

wished in life, and could calmly and deliberately desire that his life, as he had hitherto known it, should endure for ever or repeat itself ever anew, and whose love of life was so great that he willingly and gladly accepted all the hardships and miseries to which it is exposed for the sake of its pleasures, — such a man would stand “with firm-knit bones on the well-rounded, enduring earth,” and would have nothing to fear. Armed with the knowledge we have given him, he would await with indifference the death that hastens towards him on the wings of time. He would regard it as a false illusion, an impotent spectre, which frightens the weak but has no power over him who knows that he is himself the will of which the whole world is the objectification or copy, and that therefore he is always certain of life, and also of the present, the peculiar and only form of the phenomenon of the will. He could not be terrified by an endless past or future in which he would not be, for this he would regard as the empty delusion of the web of Mâya. Thus he would no more fear death than the sun fears the night. In the “Bhagavad-Gita” Krishna thus raises the mind of his young pupil Arjuna, when, seized with compunction at the sight of the arrayed hosts (somewhat as Xerxes was), he loses heart and desires to give up the battle in order to avert the death of so many thousands. Krishna leads him to this point of view, and the death of those thousands can no longer restrain him; he gives the sign for battle. This point of view is also expressed by Goethe’s Prometheus, especially when he says —

“Here sit I, form mankind
In my own image,
A race like to myself,
To suffer and to weep,
Rejoice, enjoy,
And heed thee not,
As I.”

The philosophy of Bruno and that of Spinoza might also lead any one to this point of view whose conviction was not shaken and weakened by their errors and imperfections. That of Bruno has properly no ethical theory at all, and the theory contained in the philosophy of Spinoza does not really proceed from the inner nature of his doctrine, but is merely tacked on to it by means of weak and palpable sophisms, though in itself it is praiseworthy and beautiful. Finally, there are many men who would occupy this point of view if their knowledge kept pace with their will, *i.e.*, if, free from all

illusion, they were in a position to become clearly and distinctly themselves. For this is, for knowledge, the point of view of the complete *assertion of the will to live*.

That the will asserts itself means, that while in its objectivity, *i.e.*, in the world and life, its own nature is completely and distinctly given it as idea, this knowledge does not by any means check its volition; but this very life, so known, is willed as such by the will with knowledge, consciously and deliberately, just as up to this point it willed it as blind effort without knowledge. The opposite of this, the *denial of the will to live*, shows itself if, when that knowledge is attained, volition ends, because the particular known phenomena no longer act as *motives* for willing, but the whole knowledge of the nature of the world, the mirror of the will, which has grown up through the comprehension of the *Ideas*, becomes a *quieter* of the will; and thus free, the will suppresses itself. These quite unfamiliar conceptions are difficult to understand when expressed in this general way, but it is hoped they will become clear through the exposition we shall give presently, with special reference to action, of the phenomena in which, on the one hand, the assertion in its different grades, and, on the other hand, the denial, expresses itself. For both proceed from knowledge, yet not from abstract knowledge, which is expressed in words, but from living knowledge, which is expressed in action and behaviour alone, and is independent of the dogmas which at the same time occupy the reason as abstract knowledge. To exhibit them both, and bring them to distinct knowledge of the reason, can alone be my aim, and not to prescribe or recommend the one or the other, which would be as foolish as it would be useless; for the will in itself is absolutely free and entirely self-determining, and for it there is no law. But before we go on to the exposition referred to, we must first explain and more exactly define this *freedom* and its relation to necessity. And also, with regard to the life, the assertion and denial of which is our problem, we must insert a few general remarks connected with the will and its objects. Through all this we shall facilitate the apprehension of the inmost nature of the knowledge we are aiming at, of the ethical significance of methods of action.

Since, as has been said, this whole work is only the unfolding of a single thought, it follows that all its parts have the most intimate connection with each other. Not merely that each part stands in a necessary relation to what immediately precedes it, and only presupposes a recollection of that by the

reader, as is the case with all philosophies which consist merely of a series of inferences, but that every part of the whole work is related to every other part and presupposes it. It is, therefore, necessary that the reader should remember not only what has just been said, but all the earlier parts of the work, so that he may be able to connect them with what he is reading, however much may have intervened. Plato also makes this demand upon his readers through the intricate digressions of his dialogues, in which he only returns to the leading thought after long episodes, which illustrate and explain it. In our case this demand is necessary; for the breaking up of our one single thought into its many aspects is indeed the only means of imparting it, though not essential to the thought itself, but merely an artificial form. The division of four principal points of view into four books, and the most careful bringing together of all that is related and homogeneous, assists the exposition and its comprehension; yet the material absolutely does not admit of an advance in a straight line, such as the progress of history, but necessitates a more complicated exposition. This again makes a repeated study of the book necessary, for thus alone does the connection of all the parts with each other become distinct, and only then do they all mutually throw light upon each other and become quite clear.[68]

§ 55. That the will as such is *free*, follows from the fact that, according to our view, it is the thing-in-itself, the content of all phenomena. The phenomena, on the other hand, we recognise as absolutely subordinate to the principle of sufficient reason in its four forms. And since we know that necessity is throughout identical with following from given grounds, and that these are convertible conceptions, all that belongs to the phenomenon, *i.e.*, all that is object for the knowing subject as individual, is in one aspect reason, and in another aspect consequent; and in this last capacity is determined with absolute necessity, and can, therefore, in no respect be other than it is. The whole content of Nature, the collective sum of its phenomena, is thus throughout necessary, and the necessity of every part, of every phenomenon, of every event, can always be proved, because it must be possible to find the reason from which it follows as a consequent. This admits of no exception: it follows from the unrestricted validity of the principle of sufficient reason. In another aspect, however, the same world is for us, in all its phenomena, objectivity of will. And the will, since it is not phenomenon, is not idea or object, but thing-in-itself, and is not subordinate to the principle of sufficient reason, the form of all object; thus is not

determined as a consequent through any reason, knows no necessity, *i.e.*, is *free*. The concept of freedom is thus properly a negative concept, for its content is merely the denial of necessity, *i.e.*, the relation of consequent to its reason, according to the principle of sufficient reason. Now here lies before us in its most distinct form the solution of that great contradiction, the union of freedom with necessity, which has so often been discussed in recent times, yet, so far as I know, never clearly and adequately. Everything is as phenomenon, as object, absolutely necessary: *in itself* it is will, which is perfectly free to all eternity. The phenomenon, the object, is necessarily and unalterably determined in that chain of causes and effects which admits of no interruption. But the existence in general of this object, and its specific nature, *i.e.*, the Idea which reveals itself in it, or, in other words, its character, is a direct manifestation of will. Thus, in conformity with the freedom of this will, the object might not be at all, or it might be originally and essentially something quite different from what it is, in which case, however, the whole chain of which it is a link, and which is itself a manifestation of the same will, would be quite different also. But once there and existing, it has entered the chain of causes and effects, is always necessarily determined in it, and can, therefore, neither become something else, *i.e.*, change itself, nor yet escape from the chain, *i.e.*, vanish. Man, like every other part of Nature, is objectivity of the will; therefore all that has been said holds good of him. As everything in Nature has its forces and qualities, which react in a definite way when definitely affected, and constitute its character, man also has his *character*, from which the motives call forth his actions with necessity. In this manner of conduct his empirical character reveals itself, but in this again his intelligible character, the will in itself, whose determined phenomenon he is. But man is the most complete phenomenon of will, and, as we explained in the Second Book, he had to be enlightened with so high a degree of knowledge in order to maintain himself in existence, that in it a perfectly adequate copy or repetition of the nature of the world under the form of the idea became possible: this is the comprehension of the Ideas, the pure mirror of the world, as we learnt in the Third Book. Thus in man the will can attain to full self-consciousness, to distinct and exhaustive knowledge of its own nature, as it mirrors itself in the whole world. We saw in the preceding book that art springs from the actual presence of this degree of knowledge; and at the end of our whole work it will further appear that, through the same knowledge, in that the

will relates it to itself, a suppression and self-denial of the will in its most perfect manifestation is possible. So that the freedom which otherwise, as belonging to the thing-in-itself, can never show itself in the phenomenon, in such a case does also appear in it, and, by abolishing the nature which lies at the foundation of the phenomenon, while the latter itself still continues to exist in time, it brings about a contradiction of the phenomenon with itself, and in this way exhibits the phenomena of holiness and self-renunciation. But all this can only be fully understood at the end of this book. What has just been said merely affords a preliminary and general indication of how man is distinguished from all the other phenomena of will by the fact that freedom, *i.e.*, independence of the principle of sufficient reason, which only belongs to the will as thing-in-itself, and contradicts the phenomenon, may yet possibly, in his case, appear in the phenomenon also, where, however, it necessarily exhibits itself as a contradiction of the phenomenon with itself. In this sense, not only the will in itself, but man also may certainly be called free, and thus distinguished from all other beings. But how this is to be understood can only become clear through all that is to follow, and for the present we must turn away from it altogether. For, in the first place, we must beware of the error that the action of the individual definite man is subject to no necessity, *i.e.*, that the power of the motive is less certain than the power of the cause, or the following of the conclusion from the premises. The freedom of the will as thing-in-itself, if, as has been said, we abstract from the entirely exceptional case mentioned above, by no means extends directly to its phenomenon, not even in the case in which this reaches the highest made of its visibility, and thus does not extend to the rational animal endowed with individual character, *i.e.*, the person. The person is never free although he is the phenomenon of a free will; for he is already the determined phenomenon of the free volition of this will, and, because he enters the form of every object, the principle of sufficient reason, he develops indeed the unity of that will in a multiplicity of actions, but on account of the timeless unity of that volition in itself, this multiplicity exhibits in itself the regular conformity to law of a force of Nature. Since, however, it is that free volition that becomes visible in the person and the whole of his conduct, relating itself to him as the concept to the definition, every individual action of the person is to be ascribed to the free will, and directly proclaims itself as such in consciousness. Therefore, as was said in the Second Book, every one regards himself *a priori* (*i.e.*,

here in this original feeling) as free in his individual actions, in the sense that in every given case every action is possible for him, and he only recognises *a posteriori* from experience and reflection upon experience that his actions take place with absolute necessity from the coincidence of his character with his motives. Hence it arises that every uncultured man, following his feeling, ardently defends complete freedom in particular actions, while the great thinkers of all ages, and indeed the more profound systems of religion, have denied it. But whoever has come to see clearly that the whole nature of man is will, and he himself only a phenomenon of this will, and that such a phenomenon has, even from the subject itself, the principle of sufficient reason as its necessary form, which here appears as the law of motivation, — such a man will regard it as just as absurd to doubt the inevitable nature of an action when the motive is presented to a given character, as to doubt that the three angles of any triangle are together equal to two right angles. Priestley has very sufficiently proved the necessity of the individual action in his "Doctrine of Philosophical Necessity;" but Kant, whose merit in this respect is specially great, first proved the coexistence of this necessity with the freedom of the will in itself, *i.e.*, apart from the phenomenon,[69] by establishing the distinction between the intelligible and the empirical character. I entirely adhere to this distinction, for the former is the will as thing-in-itself so far as it appears in a definite individual in a definite grade, and the latter is this phenomenon itself as it exhibits itself in time in the mode of action, and in space in the physical structure. In order to make the relation of the two comprehensible, the best expression is that which I have already used in the introductory essay, that the intelligible character of every man is to be regarded as an act of will outside time, and therefore indivisible and unchangeable, and the manifestation of this act of will developed and broken up in time and space and all the forms of the principle of sufficient reason is the empirical character as it exhibits itself for experience in the whole conduct and life of this man. As the whole tree is only the constantly repeated manifestation of one and the same tendency, which exhibits itself in its simplest form in the fibre, and recurs and is easily recognised in the construction of the leaf, shoot, branch, and trunk, so all a man's deeds are merely the constantly repeated expression, somewhat varied in form, of his intelligible character, and the induction based on the sum of all these expressions gives us his

empirical character. For the rest, I shall not at this point repeat in my own words Kant's masterly exposition, but presuppose it as known.

In the year 1840 I dealt with the important chapter on the freedom of the will, thoroughly and in detail, in my crowned prize-essay upon the subject, and exposed the reason of the delusion which led men to imagine that they found an empirically given absolute freedom of the will, that is to say, a *liberum arbitrium indifferentiæ*, as a fact in self-consciousness; for the question propounded for the essay was with great insight directed to this point. Therefore, as I refer the reader to that work, and also to the tenth paragraph of the prize-essay on the basis of morals, which was published along with it under the title "The Two Fundamental Problems of Ethics," I now omit the incomplete exposition of the necessity of the act of will, which was given at this place in the first edition. Instead of it I shall explain the delusion mentioned above in a brief discussion which is presupposed in the nineteenth chapter of the supplement to the present work, and therefore could not be given in the prize-essay referred to.

Apart from the fact that the will as the true thing-in-itself is actually original and independent, and that the feeling of its originality and absoluteness must accompany its acts in self-consciousness, though here they are already determined, there arises the illusion of an empirical freedom of the will (instead of the transcendental freedom which alone is to be attributed to it), and thus a freedom of its particular actions, from that attitude of the intellect towards the will which is explained, separated, and subordinated in the nineteenth chapter of the supplement, especially under No. 3. The intellect knows the conclusions of the will only *a posteriori* and empirically; therefore when a choice is presented, it has no data as to how the will is to decide. For the intelligible character, by virtue of which, when motives are given, only *one* decision is possible and is therefore necessary, does not come within the knowledge of the intellect, but merely the empirical character is known to it through the succession of its particular acts. Therefore it seems to the intellect that in a given case two opposite decisions are possible for the will. But this is just the same thing as if we were to say of a perpendicular beam that has lost its balance, and is hesitating which way to fall, "It can fall either to the right hand or the left." This *can* has merely a subjective significance, and really means "as far as the data known to us are concerned." Objectively, the direction of the fall is necessarily determined as soon as the equilibrium is lost. Accordingly, the

decision of one's own will is undetermined only to the beholder, one's own intellect, and thus merely relatively and subjectively for the subject of knowing. In itself and objectively, on the other hand, in every choice presented to it, its decision is at once determined and necessary. But this determination only comes into consciousness through the decision that follows upon it. Indeed, we receive an empirical proof of this when any difficult and important choice lies before us, but only under a condition which is not yet present, but merely hoped for, so that in the meanwhile we can do nothing, but must remain passive. Now we consider how we shall decide when the circumstances occur that will give us a free activity and choice. Generally the foresight of rational deliberation recommends one decision, while direct inclination leans rather to the other. So long as we are compelled to remain passive, the side of reason seems to wish to keep the upper hand; but we see beforehand how strongly the other side will influence us when the opportunity for action arises. Till then we are eagerly concerned to place the motives on both sides in the clearest light, by calm meditation on the *pro et contra*, so that every motive may exert its full influence upon the will when the time arrives, and it may not be misled by a mistake on the part of the intellect to decide otherwise than it would have done if all the motives had their due influence upon it. But this distinct unfolding of the motives on both sides is all that the intellect can do to assist the choice. It awaits the real decision just as passively and with the same intense curiosity as if it were that of a foreign will. Therefore from its point of view both decisions must seem to it equally possible; and this is just the illusion of the empirical freedom of the will. Certainly the decision enters the sphere of the intellect altogether empirically, as the final conclusion of the matter; but yet it proceeded from the inner nature, the intelligible character, of the individual will in its conflict with given motives, and therefore with complete necessity. The intellect can do nothing more than bring out clearly and fully the nature of the motives; it cannot determine the will itself; for the will is quite inaccessible to it, and, as we have seen, cannot be investigated.

If, under the same circumstances, a man could act now one way and now another, it would be necessary that his will itself should have changed in the meantime, and thus that it should lie in time, for change is only possible in time; but then either the will would be a mere phenomenon, or time would be a condition of the thing-in-itself. Accordingly the dispute as to the

freedom of the particular action, the *liberum arbitrium indifferentiæ*, really turns on the question whether the will lies in time or not. If, as both Kant's doctrine and the whole of my system necessitates, the will is the thing-in-itself outside time and outside every form of the principle of sufficient reason, not only must the individual act in the same way in the same circumstances, and not only must every bad action be the sure warrant of innumerable others, which the individual *must* perform and *cannot* leave, but, as Kant said, if only the empirical character and the motives were completely given, it would be possible to calculate the future conduct of a man just as we can calculate an eclipse of the sun or moon. As Nature is consistent, so is the character; every action must take place in accordance with it, just as every phenomenon takes place according to a law of Nature: the causes in the latter case and the motives in the former are merely the occasional causes, as was shown in the Second Book. The will, whose phenomenon is the whole being and life of man, cannot deny itself in the particular case, and what the man wills on the whole, that will he also will in the particular case.

The assertion of an empirical freedom of the will, a *liberum arbitrium indifferentiæ*, agrees precisely with the doctrine that places the inner nature of man in a *soul*, which is originally a *knowing*, and indeed really an abstract *thinking* nature, and only in consequence of this a *willing* nature — a doctrine which thus regards the will as of a secondary or derivative nature, instead of knowledge which is really so. The will indeed came to be regarded as an act of thought, and to be identified with the judgment, especially by Descartes and Spinoza. According to this doctrine every man must become what he is only through his knowledge; he must enter the world as a moral cipher come to know the things in it, and thereupon determine to be this or that, to act thus or thus, and may also through new knowledge achieve a new course of action, that is to say, become another person. Further, he must first know a thing to be *good*, and in consequence of this will it, instead of first *willing* it, and in consequence of this calling it *good*. According to my fundamental point of view, all this is a reversal of the true relation. Will is first and original; knowledge is merely added to it as an instrument belonging to the phenomenon of will. Therefore every man is what he is through his will, and his character is original, for willing is the basis of his nature. Through the knowledge which is added to it he comes to know in the course of experience *what he is*, *i.e.*, he learns his character.

Thus he *knows* himself in consequence of and in accordance with the nature of his will, instead of *willing* in consequence of and in accordance with his knowing. According to the latter view, he would only require to consider how he would like best to be, and he would be it; that is its doctrine of the freedom of the will. Thus it consists really in this, that a man is his own work guided by the light of knowledge. I, on the contrary, say that he is his own work before all knowledge, and knowledge is merely added to it to enlighten it. Therefore he cannot resolve to be this or that, nor can he become other than he is; but he *is* once for all, and he knows in the course of experience *what* he is. According to one doctrine he *wills* what he knows, and according to the other he *knows* what he wills.

The Greeks called the character ηθος, and its expression, *i.e.*, morals, ηθη. But this word comes from εθος, custom; they chose it in order to express metaphorically the constancy of character through the constancy of custom. Το γαρ ηθος απο του εθους εχει την επωνυμιαν. ηθικε γαρ καλειται δια το εθιζεσθαι (*a voce* ηθος, *i.e.*, *consuetudo* ηθος *est appellatum: ethica ergo dicta est* απο του εθιζεσθαι, *sivi ab assuescendo*) says Aristotle (Eth. Magna, i. 6, p. 1186, and Eth. Eud., p. 1220, and Eth. Nic., p. 1103, ed. Ber.) Stobæus quotes: οἱ δε κατα Ζηνωνα τροπικως; ηθος εστι πηγη βιου αφ᾽ ἡς αἱ κατα μερος πραξεις ρεουσι (*Stoici autem, Zenonis castra sequentes, metaphorice ethos definiunt vitæ fontem, e quo singulæ manant actiones*), ii. ch. 7. In Christian theology we find the dogma of predestination in consequence of election and non-election (Rom. ix. 11-24), clearly originating from the knowledge that man does not change himself, but his life and conduct, *i.e.*, his empirical character, is only the unfolding of his intelligible character, the development of decided and unchangeable natural dispositions recognisable even in the child; therefore, as it were, even at his birth his conduct is firmly determined, and remains essentially the same to the end. This we entirely agree with; but certainly the consequences which followed from the union of this perfectly correct insight with the dogmas that already existed in Jewish theology, and which now gave rise to the great difficulty, the Gordian knot upon which most of the controversies of the Church turned, I do not undertake to defend, for even the Apostle Paul scarcely succeeded in doing so by means of his simile of the potter's vessels which he invented for the purpose, for the result he finally arrived at was nothing else than this: —

“Let mankind
Fear the gods!
They hold the power
In everlasting hands:
And they can use it
As seems good to them.”

Such considerations, however, are really foreign to our subject. Some explanation as to the relation between the character and the knowledge in which all its motives lie, will now be more to the point.

The motives which determine the manifestation of the character or conduct influence it through the medium of knowledge. But knowledge is changeable, and often vacillates between truth and error, yet, as a rule, is rectified more and more in the course of life, though certainly in very different degrees. Therefore the conduct of a man may be observably altered without justifying us in concluding that his character has been changed. What the man really and in general wills, the striving of his inmost nature, and the end he pursues in accordance with it, this we can never change by influence upon him from without by instruction, otherwise we could transform him. Seneca says admirably, *velle non discitur*; whereby he preferred truth to his Stoic philosophers, who taught διδακτην ειναι την αρετην (*doceri posse virtutem*). From without the will can only be affected by motives. But these can never change the will itself; for they have power over it only under the presupposition that it is precisely such as it is. All that they can do is thus to alter the direction of its effort, *i.e.*, bring it about that it shall seek in another way than it has hitherto done that which it invariably seeks. Therefore instruction, improved knowledge, in other words, influence from without, may indeed teach the will that it erred in the means it employed, and can therefore bring it about that the end after which it strives once for all according to its inner nature shall be pursued on an entirely different path and in an entirely different object from what has hitherto been the case. But it can never bring about that the will shall will something actually different from what it has hitherto willed; this remains unchangeable, for the will is simply this willing itself, which would have to be abolished. The former, however, the possible modification of knowledge, and through knowledge of conduct, extends so far that the will seeks to attain its unalterable end, for example, Mohammed’s paradise, at one time in the real world, at another time in a world of imagination, adapting the

means to each, and thus in the first case applying prudence, might, and fraud, and in the second case, abstinence, justice, alms, and pilgrimages to Mecca. But its effort itself has not therefore changed, still less the will itself. Thus, although its action certainly shows itself very different at different times, its willing has yet remained precisely the same. *Velle non discitur.*

For motives to act, it is necessary not only that they should be present, but that they should be known; for, according to a very good expression of the schoolmen, which we referred to once before, *causa finalis movet non secundum suum esse reale; sed secundum esse cognitum*. For example, in order that the relation may appear that exists in a given man between egoism and sympathy, it is not sufficient that he should possess wealth and see others in want, but he must also know what he can do with his wealth, both for himself and for others: not only must the suffering of others be presented to him, but he must know both what suffering and also what pleasure is. Perhaps, on a first occasion, he did not know all this so well as on a second; and if, on a similar occasion, he acts differently, this arises simply from the fact that the circumstances were really different, as regards the part of them that depends on his knowing them, although they seem to be the same. As ignorance of actually existing circumstances robs them of their influence, so, on the other hand, entirely imaginary circumstances may act as if they were real, not only in the case of a particular deception, but also in general and continuously. For example, if a man is firmly persuaded that every good action will be repaid him a hundredfold in a future life, such a conviction affects him in precisely the same way as a good bill of exchange at a very long date, and he can give from mere egoism, as from another point of view he would take from egoism. He has not changed himself: *velle non discitur.* It is on account of this great influence of knowledge upon action, while the will remains unchangeable, that the character develops and its different features appear only little by little. Therefore it shows itself different at every period of life, and an impetuous, wild youth may be succeeded by a staid, sober, manly age. Especially what is bad in the character will always come out more strongly with time, yet sometimes it occurs that passions which a man gave way to in his youth are afterwards voluntarily restrained, simply because the motives opposed to them have only then come into knowledge. Hence, also, we are all innocent to begin with, and this merely means that neither we nor others know the

evil of our own nature; it only appears with the motives, and only in time do the motives appear in knowledge. Finally we come to know ourselves as quite different from what *a priori* we supposed ourselves to be, and then we are often terrified at ourselves.

Repentance never proceeds from a change of the will (which is impossible), but from a change of knowledge. The essential and peculiar in what I have always willed I must still continue to will; for I myself am this will which lies outside time and change. I can therefore never repent of what I have willed, though I can repent of what I have done; because, led by false conceptions, I did something that was not in conformity with my will. The discovery of this through fuller knowledge is *repentance*. This extends not merely to worldly wisdom, to the choice of the means, and the judgment of the appropriateness of the end to my own will, but also to what is properly ethical. For example, I may have acted more egotistically than is in accordance with my character, led astray by exaggerated ideas of the need in which I myself stood, or of the craft, falseness, and wickedness of others, or because I hurried too much, *i.e.*, acted without deliberation, determined not by motives distinctly known *in abstracto*, but by merely perceived motives, by the present and the emotion which it excited, and which was so strong that I had not properly the use of my reason; but the return of reflection is thus here also merely corrected knowledge, and from this repentance may proceed, which always proclaims itself by making amends for the past, as far as is possible. Yet it must be observed that, in order to deceive themselves, men prearrange what seem to be hasty errors, but are really secretly considered actions. For we deceive and flatter no one through such fine devices as ourselves. The converse of the case we have given may also occur. I may be misled by too good an opinion of others, or want of knowledge of the relative value of the good things of life, or some abstract dogma in which I have since lost faith, and thus I may act less egotistically than is in keeping with my character, and lay up for myself repentance of another kind. Thus repentance is always corrected knowledge of the relation of an act to its special intention. When the will reveals its Ideas in space alone, *i.e.*, through mere form, the matter in which other Ideas — in this case natural forces — already reign, resists the will, and seldom allows the form that is striving after visibility to appear in perfect purity and distinctness, *i.e.*, in perfect beauty. And there is an analogous hindrance to the will as it reveals itself in time alone, *i.e.*, through actions, in the

knowledge which seldom gives it the data quite correctly, so that the action which takes place does not accurately correspond to the will, and leads to repentance. Repentance thus always proceeds from corrected knowledge, not from the change of the will, which is impossible. Anguish of conscience for past deeds is anything but repentance. It is pain at the knowledge of oneself in one's inmost nature, *i.e.*, as will. It rests precisely on the certainty that we have still the same will. If the will were changed, and therefore the anguish of conscience mere repentance, it would cease to exist. The past could then no longer give us pain, for it exhibited the expressions of a will which is no longer that of him who has repented. We shall explain the significance of anguish of conscience in detail farther on.

The influence which knowledge, as the medium of motives, exerts, not indeed upon the will itself, but upon its appearance in actions, is also the source of the principal distinction between the action of men and that of brutes, for their methods of knowledge are different. The brute has only knowledge of perception, the man, through reason, has also abstract ideas, conceptions. Now, although man and brute are with equal necessity determined by their motives, yet man, as distinguished from the brute, has a complete *choice*, which has often been regarded as a freedom of the will in particular actions, although it is nothing but the possibility of a thoroughly-fought-out battle between several motives, the strongest of which then determines it with necessity. For this the motives must have assumed the form of abstract thoughts, because it is really only by means of these that deliberation, *i.e.*, a weighing of opposite reasons for action, is possible. In the case of the brute there can only be a choice between perceptible motives presented to it, so that the choice is limited to the narrow sphere of its present sensuous perception. Therefore the necessity of the determination of the will by the motive, which is like that of the effect by the cause, can be exhibited perceptibly and directly only in the case of the brutes, because here the spectator has the motives just as directly before his eyes as their effect; while in the case of man the motives are almost always abstract ideas, which are not communicated to the spectator, and even for the actor himself the necessity of their effect is hidden behind their conflict. For only *in abstracto* can several ideas, as judgments and chains of conclusions, lie beside each other in consciousness, and then, free from all determination of time, work against each other till the stronger overcomes the rest and determines the will. This is the complete *choice* or power of deliberation

which man has as distinguished from the brutes, and on account of which freedom of the will has been attributed to him, in the belief that his willing is a mere result of the operations of his intellect, without a definite tendency which serves as its basis; while, in truth, the motives only work on the foundation and under the presupposition of his definite tendency, which in his case is individual, *i.e.*, a character. A fuller exposition of this power of deliberation, and the difference between human and brute choice which is introduced by it, will be found in the "Two Fundamental Problems of Ethics" (1st edition, p. 35, *et seq.*; 2d edition, p. 34, *et seq.*), to which I therefore refer. For the rest, this power of deliberation which man possesses is one of those things that makes his existence so much more miserable than that of the brute. For in general our greatest sufferings do not lie in the present as ideas of perception or as immediate feelings; but in the reason, as abstract conceptions, painful thoughts, from which the brute, which lives only in the present, and therefore in enviable carelessness, is entirely free.

It seems to have been the dependence, which we have shown, of the human power of deliberation upon the faculty of abstract thinking, and thus also of judging and drawing conclusions also, that led both Descartes and Spinoza to identify the decisions of the will with the faculty of asserting and denying (the faculty of judgment). From this Descartes deduced the doctrine that the will, which, according to him, is indifferently free, is the source of sin, and also of all theoretical error. And Spinoza, on the other hand, concluded that the will is necessarily determined by the motives, as the judgment is by the reasons.[70] The latter doctrine is in a sense true, but it appears as a true conclusion from false premises.

The distinction we have established between the ways in which the brutes and man are respectively moved by motives exerts a very wide influence upon the nature of both, and has most to do with the complete and obvious differences of their existence. While an idea of perception is in every case the motive which determines the brute, the man strives to exclude this kind of motivation altogether, and to determine himself entirely by abstract ideas. Thus he uses his prerogative of reason to the greatest possible advantage. Independent of the present, he neither chooses nor avoids the passing pleasure or pain, but reflects on the consequences of both. In most cases, setting aside quite insignificant actions, we are determined by abstract, thought motives, not present impressions. Therefore all particular privation for the moment is for us comparatively light, but all

renunciation is terribly hard; for the former only concerns the fleeting present, but the latter concerns the future, and includes in itself innumerable privations, of which it is the equivalent. The causes of our pain, as of our pleasure, lie for the most part, not in the real present, but merely in abstract thoughts. It is these which are often unbearable to us — inflict torments in comparison with which all the sufferings of the animal world are very small; for even our own physical pain is not felt at all when they are present. Indeed, in the case of keen mental suffering, we even inflict physical suffering on ourselves merely to distract our attention from the former to the latter. This is why, in great mental anguish, men tear their hair, beat their breasts, lacerate their faces, or roll on the floor, for all these are in reality only violent means of diverting the mind from an unbearable thought. Just because mental pain, being much greater, makes us insensible to physical pain, suicide is very easy to the person who is in despair, or who is consumed by morbid depression, even though formerly, in comfortable circumstances, he recoiled at the thought of it. In the same way care and passion (thus the play of thought) wear out the body oftener and more than physical hardships. And in accordance with this Epictetus rightly says: Ταρασσει τους ανθρωπους ου τα πραγματα, αλλα τα περι των πραγματων δογματα (*Perturbant homines non res ipsæ, sed de rebus decreta*) (V.); and Seneca: *Plura sunt quæ nos terrent, quam quæ premunt, et sæpius opinione quam re laboramus* (Ep. 5). Eulenspiegel also admirably bantered human nature, for going uphill he laughed, and going downhill he wept. Indeed, children who have hurt themselves often cry, not at the pain, but at the thought of the pain which is awakened when some one condoles with them. Such great differences in conduct and in life arise from the diversity between the methods of knowledge of the brutes and man. Further, the appearance of the distinct and decided individual character, the principal distinction between man and the brute, which has scarcely more than the character of the species, is conditioned by the choice between several motives, which is only possible through abstract conceptions. For only after a choice has been made are the resolutions, which vary in different individuals, an indication of the individual character which is different in each; while the action of the brute depends only upon the presence or absence of the impression, supposing this impression to be in general a motive for its species. And, finally, in the case of man, only the resolve, and not the mere wish, is a valid indication of his character both for himself and

for others; but the resolve becomes for himself, as for others, a certain fact only through the deed. The wish is merely the necessary consequence of the present impression, whether of the outward stimulus, or the inward passing mood; and is therefore as immediately necessary and devoid of consideration as the action of the brutes. Therefore, like the action of the brutes, it merely expresses the character of the species, not that of the individual, *i.e.*, it indicates merely what *man in general*, not what the individual who experiences the wish, is capable of doing. The deed alone, — because as human action it always requires a certain deliberation, and because as a rule a man has command of his reason, is considerate, *i.e.*, decides in accordance with considered and abstract motives, — is the expression of the intelligible maxims of his conduct, the result of his inmost willing, and is related as a letter to the word that stands for his empirical character, itself merely the temporal expression of his intelligible character. In a healthy mind, therefore, only deeds oppress the conscience, not wishes and thoughts; for it is only our deeds that hold up to us the mirror of our will. The deed referred to above, that is entirely unconsidered and is really committed in blind passion, is to a certain extent an intermediate thing between the mere wish and the resolve.

Therefore, by true repentance, which, however, shows itself as action also, it can be obliterated, as a falsely drawn line, from that picture of our will which our course of life is. I may insert the remark here, as a very good comparison, that the relation between wish and deed has a purely accidental but accurate analogy with that between the accumulation and discharge of electricity.

As the result of the whole of this discussion of the freedom of the will and what relates to it, we find that although the will may, in itself and apart from the phenomenon, be called free and even omnipotent, yet in its particular phenomena enlightened by knowledge, as in men and brutes, it is determined by motives to which the special character regularly and necessarily responds, and always in the same way. We see that because of the possession on his part of abstract or rational knowledge, man, as distinguished from the brutes, has a *choice*, which only makes him the scene of the conflict of his motives, without withdrawing him from their control. This choice is therefore certainly the condition of the possibility of the complete expression of the individual character, but is by no means to

be regarded as freedom of the particular volition, *i.e.*, independence of the law of causality, the necessity of which extends to man as to every other phenomenon. Thus the difference between human volition and that of the brutes, which is introduced by reason or knowledge through concepts, extends to the point we have indicated, and no farther. But, what is quite a different thing, there may arise a phenomenon of the human will which is quite impossible in the brute creation, if man altogether lays aside the knowledge of particular things as such which is subordinate to the principle of sufficient reason, and by means of his knowledge of the Ideas sees through the *principium individuationis*. Then an actual appearance of the real freedom of the will as a thing-in-itself is possible, by which the phenomenon comes into a sort of contradiction with itself, as is indicated by the word self-renunciation; and, finally, the "in-itself" of its nature suppresses itself. But this, the one, real, and direct expression of the freedom of the will in itself in the phenomenon, cannot be distinctly explained here, but will form the subject of the concluding part of our work.

Now that we have shown clearly in these pages the unalterable nature of the empirical character, which is just the unfolding of the intelligible character that lies outside time, together with the necessity with which actions follow upon its contact with motives, we hasten to anticipate an argument which may very easily be drawn from this in the interest of bad dispositions. Our character is to be regarded as the temporal unfolding of an extra-temporal, and therefore indivisible and unalterable, act of will, or an intelligible character. This necessarily determines all that is essential in our conduct in life, *i.e.*, its ethical content, which must express itself in accordance with it in its phenomenal appearance, the empirical character; while only what is unessential in this, the outward form of our course of life, depends upon the forms in which the motives present themselves. It might, therefore, be inferred that it is a waste of trouble to endeavour to improve one's character, and that it is wiser to submit to the inevitable, and gratify every inclination at once, even if it is bad. But this is precisely the same thing as the theory of an inevitable fate which is called αργος λογος, and in more recent times Turkish faith. Its true refutation, as it is supposed to have been given by Chrysippus, is explained by Cicero in his book *De Fato*, ch. 12, 13.

Though everything may be regarded as irrevocably predetermined by fate, yet it is so only through the medium of the chain of causes; therefore in

no case can it be determined that an effect shall appear without its cause. Thus it is not simply the event that is predetermined, but the event as the consequence of preceding causes; so that fate does not decide the consequence alone, but also the means as the consequence of which it is destined to appear. Accordingly, if some means is not present, it is certain that the consequence also will not be present: each is always present in accordance with the determination of fate, but this is never known to us till afterwards.

As events always take place according to fate, *i.e.*, according to the infinite concatenation of causes, so our actions always take place according to our intelligible character. But just as we do not know the former beforehand, so no *a priori* insight is given us into the latter, but we only come to know ourselves as we come to know other persons *a posteriori* through experience. If the intelligible character involved that we could only form a good resolution after a long conflict with a bad disposition, this conflict would have to come first and be waited for. Reflection on the unalterable nature of the character, on the unity of the source from which all our actions flow, must not mislead us into claiming the decision of the character in favour of one side or the other; it is in the resolve that follows that we shall see what manner of men we are, and mirror ourselves in our actions. This is the explanation of the satisfaction or the anguish of soul with which we look back on the course of our past life. Both are experienced, not because these past deeds have still an existence; they are past, they have been, and now are no more; but their great importance for us lies in their significance, lies in the fact that these deeds are the expression of the character, the mirror of the will, in which we look and recognise our inmost self, the kernel of our will. Because we experience this not before, but only after, it behoves us to strive and fight in time, in order that the picture we produce by our deeds may be such that the contemplation of it may calm us as much as possible, instead of harassing us. The significance of this consolation or anguish of soul will, as we have said, be inquired into farther on; but to this place there belongs the inquiry which follows, and which stands by itself.

Besides the intelligible and the empirical character, we must mention a third which is different from them both, the *acquired character*, which one only receives in life through contact with the world, and which is referred to when one is praised as a man of character or censured as being without

character. Certainly one might suppose that, since the empirical character, as the phenomenon of the intelligible, is unalterable, and, like every natural phenomenon, is consistent with itself, man would always have to appear like himself and consistent, and would therefore have no need to acquire a character artificially by experience and reflection. But the case is otherwise, and although a man is always the same, yet he does not always understand himself, but often mistakes himself, till he has in some degree acquired real self-knowledge. The empirical character, as a mere natural tendency, is in itself irrational; nay, more, its expressions are disturbed by reason, all the more so the more intellect and power of thought the man has; for these always keep before him what becomes *man in general* as the character of the species, and what is possible for him both in will and in deed. This makes it the more difficult for him to see how much his individuality enables him to will and to accomplish. He finds in himself the germs of all the various human pursuits and powers, but the difference of degree in which they exist in his individuality is not clear to him in the absence of experience; and if he now applies himself to the pursuits which alone correspond to his character, he yet feels, especially at particular moments and in particular moods, the inclination to directly opposite pursuits which cannot be combined with them, but must be entirely suppressed if he desires to follow the former undisturbed. For as our physical path upon earth is always merely a line, not an extended surface, so in life, if we desire to grasp and possess one thing, we must renounce and leave innumerable others on the right hand and on the left. If we cannot make up our minds to this, but, like children at the fair, snatch at everything that attracts us in passing, we are making the perverse endeavour to change the line of our path into an extended surface; we run in a zigzag, skip about like a will o' the wisp, and attain to nothing. Or, to use another comparison, as, according to Hobbes' philosophy of law, every one has an original right to everything but an exclusive right to nothing, yet can obtain an exclusive right to particular things by renouncing his right to all the rest, while others, on their part, do likewise with regard to what he has chosen; so is it in life, in which some definite pursuit, whether it be pleasure, honour, wealth, science, art, or virtue, can only be followed with seriousness and success when all claims that are foreign to it are given up, when everything else is renounced. Accordingly, the mere will and the mere ability are not sufficient, but a man must also *know* what he wills, and *know* what he can do; only then will he

show character, and only then can he accomplish something right. Until he attains to that, notwithstanding the natural consistency of the empirical character, he is without character. And although, on the whole, he must remain true to himself, and fulfil his course, led by his dæmon, yet his path will not be a straight line, but wavering and uneven. He will hesitate, deviate, turn back, lay up for himself repentance and pain. And all this is because, in great and small, he sees before him all that is possible and attainable for man in general, but does not know what part of all this is alone suitable for him, can be accomplished by him, and is alone enjoyable by him. He will, therefore, envy many men on account of a position and circumstances which are yet only suitable to their characters and not to his, and in which he would feel unhappy, if indeed he found them endurable at all. For as a fish is only at home in water, a bird in the air, a mole in the earth, so every man is only at home in the atmosphere suitable to him. For example, not all men can breathe the air of court life. From deficiency of proper insight into all this, many a man will make all kinds of abortive attempts, will do violence to his character in particulars, and yet, on the whole, will have to yield to it again; and what he thus painfully attains will give him no pleasure; what he thus learns will remain dead; even in an ethical regard, a deed that is too noble for his character, that has not sprung from pure, direct impulse, but from a concept, a dogma, will lose all merit, even in his own eyes, through subsequent egoistical repentance. *Velle non discitur.* We only become conscious of the inflexibility of another person's character through experience, and till then we childishly believe that it is possible, by means of rational ideas, by prayers and entreaties, by example and noble-mindedness, ever to persuade any one to leave his own way, to change his course of conduct, to depart from his mode of thinking, or even to extend his capacities: so is it also with ourselves. We must first learn from experience what we desire and what we can do. Till then we know it not, we are without character, and must often be driven back to our own way by hard blows from without. But if we have finally learnt it, then we have attained to what in the world is called character, the *acquired character*. This is accordingly nothing but the most perfect knowledge possible of our own individuality. It is the abstract, and consequently distinct, knowledge of the unalterable qualities of our own empirical character, and of the measure and direction of our mental and physical powers, and thus of the whole strength and weakness of our own

individuality. This places us in a position to carry out deliberately and methodically the rôle which belongs to our own person, and to fill up the gaps which caprices or weaknesses produce in it, under the guidance of fixed conceptions. This rôle is in itself unchangeably determined once for all, but hitherto we have allowed it to follow its natural course without any rule. We have now brought to distinct conscious maxims which are always present to us the form of conduct which is necessarily determined by our own individual nature, and now we conduct it in accordance with them as deliberately as if we had learned it; without ever falling into error through the passing influence of the mood or the impression of the present, without being checked by the bitterness or sweetness of some particular thing we meet with on our path, without delay, without hesitation, without inconsistency. We shall now no longer, as novices, wait, attempt, and grope about in order to see what we really desire and are able to do, but we know this once for all, and in every choice we have only to apply general principles to particular cases, and arrive at once at a decision. We know our will in general, and do not allow ourselves to be led by the passing mood or by solicitations from without to resolve in particular cases what is contrary to it as a whole. We know in the same way the nature and the measure of our strength and our weakness, and thereby are spared much suffering. For we experience no real pleasure except in the use and feeling of our own powers, and the greatest pain is the conscious deficiency of our powers where we need them. If, now, we have discovered where our strength and our weakness lie, we will endeavour to cultivate, employ, and in every way make use of those talents which are naturally prominent in us. We will always turn to those occupations in which they are valuable and to the purpose, and entirely avoid, even with self-renunciation, those pursuits for which we have naturally little aptitude; we will beware of attempting that in which we have no chance of succeeding. Only he who has attained to this will constantly and with full consciousness be completely himself, and will never fail himself at the critical moment, because he will always have known what he could expect from himself. He will often enjoy the satisfaction of feeling his strength, and seldom experience the pain of being reminded of his weakness. The latter is mortification, which causes perhaps the greatest of mental sufferings; therefore it is far more endurable to have our misfortune brought clearly before us than our incapacity. And, further, if we are thus fully acquainted with our strength and our weakness, we will

not attempt to make a show of powers which we do not possess; we will not play with base coin, for all such dissimulation misses the mark in the end. For since the whole man is only the phenomenon of his will, nothing can be more perverse than to try, by means of reflection, to become something else than one is, for this is a direct contradiction of the will with itself. The imitation of the qualities and idiosyncrasies of others is much more shameful than to dress in other people's clothes; for it is the judgment of our own worthlessness pronounced by ourselves. Knowledge of our own mind and its capacities of every kind, and their unalterable limits, is in this respect the surest way to the attainment of the greatest possible contentment with ourselves. For it holds good of inward as of outward circumstances that there is for us no consolation so effective as the complete certainty of unalterable necessity. No evil that befalls us pains us so much as the thought of the circumstances by which it might have been warded off. Therefore nothing comforts us so effectually as the consideration of what has happened from the standpoint of necessity, from which all accidents appear as tools in the hand of an overruling fate, and we therefore recognise the evil that has come to us as inevitably produced by the conflict of inner and outer circumstances; in other words, fatalism. We really only complain and storm so long as we hope either to affect others or to excite ourselves to unheard-of efforts. But children and grown-up people know very well to yield contentedly as soon as they clearly see that it absolutely cannot be otherwise: — Θυμὸν ἐνὶ στήθεσσι φίλον δαμάσσαντες ἀνάγκῃ (*Animo in pectoribus nostro domito necessitate*). We are like the entrapped elephants, that rage and struggle for many days, till they see that it is useless, and then suddenly offer their necks quietly to the yoke, tamed for ever. We are like King David, who, as long as his son still lived, unceasingly importuned Jehovah with prayers, and behaved himself as if in despair; but as soon as his son was dead, thought no longer about it. Hence it arises that innumerable permanent ills, such as lameness, poverty, low estate, ugliness, a disagreeable dwelling-place, are borne with indifference by innumerable persons, and are no longer felt, like healed wounds, just because these persons know that inward or outward necessity renders it impossible that any change can take place in these things; while those who are more fortunate cannot understand how such misfortunes can be borne. Now as with outward necessity, so also with inward; nothing reconciles so thoroughly as a distinct knowledge of it. If we have once for all distinctly

recognised not only our good qualities and our strength, but also our defects and weakness, established our aim accordingly, and rest satisfied concerning what cannot be attained, we thus escape in the surest way, as far as our individuality permits, the bitterest of all sorrows, discontentment with ourselves, which is the inevitable result of ignorance of our own individuality, of false conceit and the audacity that proceeds from it. To the bitter chapter of the self-knowledge here recommended the lines of Ovid admit of excellent application —

"*Optimus ille animi vindex lædentia pectus,*
Vincula qui rupit, dedoluitque semel."

So much with regard to the *acquired character*, which, indeed, is not of so much importance for ethics proper as for life in the world. But its investigation was related as that of a third species to the investigation of the intelligible and the empirical character, in regard to which we were obliged to enter upon a somewhat detailed inquiry in order to bring out clearly how in all its phenomena the will is subject to necessity, while yet in itself it may be called free and even omnipotent.

§ 56. This freedom, this omnipotence, as the expression of which the whole visible world exists and progressively develops in accordance with the laws which belong to the form of knowledge, can now, at the point at which in its most perfect manifestation it has attained to the completely adequate knowledge of its own nature, express itself anew in two ways. Either it wills here, at the summit of mental endowment and self-consciousness, simply what it willed before blindly and unconsciously, and if so, knowledge always remains its *motive* in the whole as in the particular case. Or, conversely, this knowledge becomes for it a *quieter*, which appeases and suppresses all willing. This is that assertion and denial of the will to live which was stated above in general terms. As, in the reference of individual conduct, a general, not a particular manifestation of will, it does not disturb and modify the development of the character, nor does it find its expression in particular actions; but, either by an ever more marked appearance of the whole method of action it has followed hitherto, or conversely by the entire suppression of it, it expresses in a living form the maxims which the will has freely adopted in accordance with the knowledge it has now attained to. By the explanations we have just given of freedom, necessity, and character, we have somewhat facilitated and

prepared the way for the clearer development of all this, which is the principal subject of this last book. But we shall have done so still more when we have turned our attention to life itself, the willing or not willing of which is the great question, and have endeavoured to find out generally what the will itself, which is everywhere the inmost nature of this life, will really attain by its assertion — in what way and to what extent this assertion satisfies or can satisfy the will; in short, what is generally and mainly to be regarded as its position in this its own world, which in every relation belongs to it.

First of all, I wish the reader to recall the passage with which we closed the Second Book, — a passage occasioned by the question, which met us then, as to the end and aim of the will. Instead of the answer to this question, it appeared clearly before us how, in all the grades of its manifestation, from the lowest to the highest, the will dispenses altogether with a final goal and aim. It always strives, for striving is its sole nature, which no attained goal can put an end to. Therefore it is not susceptible of any final satisfaction, but can only be restrained by hindrances, while in itself it goes on for ever. We see this in the simplest of all natural phenomena, gravity, which does not cease to strive and press towards a mathematical centre to reach which would be the annihilation both of itself and matter, and would not cease even if the whole universe were already rolled into one ball. We see it in the other simple natural phenomena. A solid tends towards fluidity either by melting or dissolving, for only so will its chemical forces be free; rigidity is the imprisonment in which it is held by cold. The fluid tends towards the gaseous state, into which it passes at once as soon as all pressure is removed from it. No body is without relationship, *i.e.*, without tendency or without desire and longing, as Jacob Böhme would say. Electricity transmits its inner self-repulsion to infinity, though the mass of the earth absorbs the effect. Galvanism is certainly, so long as the pile is working, an aimless, unceasingly repeated act of repulsion and attraction. The existence of the plant is just such a restless, never satisfied striving, a ceaseless tendency through ever-ascending forms, till the end, the seed, becomes a new starting-point; and this repeated *ad infinitum* — nowhere an end, nowhere a final satisfaction, nowhere a resting-place. It will also be remembered, from the Second Book, that the multitude of natural forces and organised forms everywhere strive with each other for the matter in which they desire to appear, for each of them only

possesses what it has wrested from the others; and thus a constant internecine war is waged, from which, for the most part, arises the resistance through which that striving, which constitutes the inner nature of everything, is at all points hindered; struggles in vain, yet, from its nature, cannot leave off; toils on laboriously till this phenomenon dies, when others eagerly seize its place and its matter.

We have long since recognised this striving, which constitutes the kernel and in-itself of everything, as identical with that which in us, where it manifests itself most distinctly in the light of the fullest consciousness, is called *will*. Its hindrance through an obstacle which places itself between it and its temporary aim we call *suffering*, and, on the other hand, its attainment of the end satisfaction, wellbeing, happiness. We may also transfer this terminology to the phenomena of the unconscious world, for though weaker in degree, they are identical in nature. Then we see them involved in constant suffering, and without any continuing happiness. For all effort springs from defect — from discontent with one's estate — is thus suffering so long as it is not satisfied; but no satisfaction is lasting, rather it is always merely the starting-point of a new effort. The striving we see everywhere hindered in many ways, everywhere in conflict, and therefore always under the form of suffering. Thus, if there is no final end of striving, there is no measure and end of suffering.

But what we only discover in unconscious Nature by sharpened observation, and with an effort, presents itself distinctly to us in the intelligent world in the life of animals, whose constant suffering is easily proved. But without lingering over these intermediate grades, we shall turn to the life of man, in which all this appears with the greatest distinctness, illuminated by the clearest knowledge; for as the phenomenon of will becomes more complete, the suffering also becomes more and more apparent. In the plant there is as yet no sensibility, and therefore no pain. A certain very small degree of suffering is experienced by the lowest species of animal life — infusoria and radiata; even in insects the capacity to feel and suffer is still limited. It first appears in a high degree with the complete nervous system of vertebrate animals, and always in a higher degree the more intelligence develops. Thus, in proportion as knowledge attains to distinctness, as consciousness ascends, pain also increases, and therefore reaches its highest degree in man. And then, again, the more distinctly a man knows, the more intelligent he is, the more pain he has; the man who is

gifted with genius suffers most of all. In this sense, that is, with reference to the degree of knowledge in general, not mere abstract rational knowledge, I understand and use here that saying of the Preacher: *Qui auget scientiam, auget at dolorem.* That philosophical painter or painting philosopher, Tischbein, has very beautifully expressed the accurate relation between the degree of consciousness and that of suffering by exhibiting it in a visible and clear form in a drawing. The upper half of his drawing represents women whose children have been stolen, and who in different groups and attitudes, express in many ways deep maternal pain, anguish, and despair. The lower half of the drawing represents sheep whose lambs have been taken away. They are arranged and grouped in precisely the same way; so that every human head, every human attitude of the upper half, has below a brute head and attitude corresponding to it. Thus we see distinctly how the pain which is possible in the dull brute consciousness is related to the violent grief, which only becomes possible through distinctness of knowledge and clearness of consciousness.

We desire to consider in this way, in *human existence*, the inner and essential destiny of will. Every one will easily recognise that same destiny expressed in various degrees in the life of the brutes, only more weakly, and may also convince himself to his own satisfaction, from the suffering animal world, *how essential to all life is suffering*.

§ 57. At every grade that is enlightened by knowledge, the will appears as an individual. The human individual finds himself as finite in infinite space and time, and consequently as a vanishing quantity compared with them. He is projected into them, and, on account of their unlimited nature, he has always a merely relative, never absolute *when* and *where* of his existence; for his place and duration are finite parts of what is infinite and boundless. His real existence is only in the present, whose unchecked flight into the past is a constant transition into death, a constant dying. For his past life, apart from its possible consequences for the present, and the testimony regarding the will that is expressed in it, is now entirely done with, dead, and no longer anything; and, therefore, it must be, as a matter of reason, indifferent to him whether the content of that past was pain or pleasure. But the present is always passing through his hands into the past; the future is quite uncertain and always short. Thus his existence, even when we consider only its formal side, is a constant hurrying of the present into the dead past, a constant dying. But if we look at it from the physical side; it is

clear that, as our walking is admittedly merely a constantly prevented falling, the life of our body is only a constantly prevented dying, an ever-postponed death: finally, in the same way, the activity of our mind is a constantly deferred ennui. Every breath we draw wards off the death that is constantly intruding upon us. In this way we fight with it every moment, and again, at longer intervals, through every meal we eat, every sleep we take, every time we warm ourselves, &c. In the end, death must conquer, for we became subject to him through birth, and he only plays for a little while with his prey before he swallows it up. We pursue our life, however, with great interest and much solicitude as long as possible, as we blow out a soap-bubble as long and as large as possible, although we know perfectly well that it will burst.

We saw that the inner being of unconscious nature is a constant striving without end and without rest. And this appears to us much more distinctly when we consider the nature of brutes and man. Willing and striving is its whole being, which may be very well compared to an unquenchable thirst. But the basis of all willing is need, deficiency, and thus pain. Consequently, the nature of brutes and man is subject to pain originally and through its very being. If, on the other hand, it lacks objects of desire, because it is at once deprived of them by a too easy satisfaction, a terrible void and ennui comes over it, *i.e.*, its being and existence itself becomes an unbearable burden to it. Thus its life swings like a pendulum backwards and forwards between pain and ennui. This has also had to express itself very oddly in this way; after man had transferred all pain and torments to hell, there then remained nothing over for heaven but ennui.

But the constant striving which constitutes the inner nature of every manifestation of will obtains its primary and most general foundation at the higher grades of objectification, from the fact that here the will manifests itself as a living body, with the iron command to nourish it; and what gives strength to this command is just that this body is nothing but the objectified will to live itself. Man, as the most complete objectification of that will, is in like measure also the most necessitous of all beings: he is through and through concrete willing and needing; he is a concretion of a thousand necessities. With these he stands upon the earth, left to himself, uncertain about everything except his own need and misery. Consequently the care for the maintenance of that existence under exacting demands, which are renewed every day, occupies, as a rule, the whole of human life. To this is

directly related the second claim, that of the propagation of the species. At the same time he is threatened from all sides by the most different kinds of dangers, from which it requires constant watchfulness to escape. With cautious steps and casting anxious glances round him he pursues his path, for a thousand accidents and a thousand enemies lie in wait for him. Thus he went while yet a savage, thus he goes in civilised life; there is no security for him.

"*Qualibus in tenebris vitæ, quantisque periclis*
Degitur hocc' ævi, quodcunque est!" — Lucr. ii. 15.

The life of the great majority is only a constant struggle for this existence itself, with the certainty of losing it at last. But what enables them to endure this wearisome battle is not so much the love of life as the fear of death, which yet stands in the background as inevitable, and may come upon them at any moment. Life itself is a sea, full of rocks and whirlpools, which man avoids with the greatest care and solicitude, although he knows that even if he succeeds in getting through with all his efforts and skill, he yet by doing so comes nearer at every step to the greatest, the total, inevitable, and irremediable shipwreck, death; nay, even steers right upon it: this is the final goal of the laborious voyage, and worse for him than all the rocks from which he has escaped.

Now it is well worth observing that, on the one hand, the suffering and misery of life may easily increase to such an extent that death itself, in the flight from which the whole of life consists, becomes desirable, and we hasten towards it voluntarily; and again, on the other hand, that as soon as want and suffering permit rest to a man, ennui is at once so near that he necessarily requires diversion. The striving after existence is what occupies all living things and maintains them in motion. But when existence is assured, then they know not what to do with it; thus the second thing that sets them in motion is the effort to get free from the burden of existence, to make it cease to be felt, "to kill time," *i.e.*, to escape from ennui. Accordingly we see that almost all men who are secure from want and care, now that at last they have thrown off all other burdens, become a burden to themselves, and regard as a gain every hour they succeed in getting through; and thus every diminution of the very life which, till then, they have employed all their powers to maintain as long as possible. Ennui is by no means an evil to be lightly esteemed; in the end it depicts on the countenance real despair. It makes beings who love each other so little as

men do, seek each other eagerly, and thus becomes the source of social intercourse. Moreover, even from motives of policy, public precautions are everywhere taken against it, as against other universal calamities. For this evil may drive men to the greatest excesses, just as much as its opposite extreme, famine: the people require *panem et circenses*. The strict penitentiary system of Philadelphia makes use of ennui alone as a means of punishment, through solitary confinement and idleness, and it is found so terrible that it has even led prisoners to commit suicide. As want is the constant scourge of the people, so ennui is that of the fashionable world. In middle-class life ennui is represented by the Sunday, and want by the six week-days.

Thus between desiring and attaining all human life flows on throughout. The wish is, in its nature, pain; the attainment soon begets satiety: the end was only apparent; possession takes away the charm; the wish, the need, presents itself under a new form; when it does not, then follows desolateness, emptiness, ennui, against which the conflict is just as painful as against want. That wish and satisfaction should follow each other neither too quickly nor too slowly reduces the suffering, which both occasion to the smallest amount, and constitutes the happiest life. For that which we might otherwise call the most beautiful part of life, its purest joy, if it were only because it lifts us out of real existence and transforms us into disinterested spectators of it — that is, pure knowledge, which is foreign to all willing, the pleasure of the beautiful, the true delight in art — this is granted only to a very few, because it demands rare talents, and to these few only as a passing dream. And then, even these few, on account of their higher intellectual power, are made susceptible of far greater suffering than duller minds can ever feel, and are also placed in lonely isolation by a nature which is obviously different from that of others; thus here also accounts are squared. But to the great majority of men purely intellectual pleasures are not accessible. They are almost quite incapable of the joys which lie in pure knowledge. They are entirely given up to willing. If, therefore, anything is to win their sympathy, to be *interesting* to them, it must (as is implied in the meaning of the word) in some way excite their *will*, even if it is only through a distant and merely problematical relation to it; the will must not be left altogether out of the question, for their existence lies far more in willing than in knowing, — action and reaction is their one element. We may find in trifles and everyday occurrences the naïve expressions of this

quality. Thus, for example, at any place worth seeing they may visit, they write their names, in order thus to react, to affect the place since it does not affect them. Again, when they see a strange rare animal, they cannot easily confine themselves to merely observing it; they must rouse it, tease it, play with it, merely to experience action and reaction; but this need for excitement of the will manifests itself very specially in the discovery and support of card-playing, which is quite peculiarly the expression of the miserable side of humanity.

But whatever nature and fortune may have done, whoever a man be and whatever he may possess, the pain which is essential to life cannot be thrown off: — Πηλειδης δ᾽ ῳμωξεν, ιδων εις ουρανον ευρυν (*Pelides autem ejulavit, intuitus in cœlum latum*). And again: — Ζηνος μεν παις ηα Κρονιονος, αυταρ οιζυν ειχον απειρεσιην (*Jovis quidem filius eram Saturnii; verum ærumnam habebam infinitam*). The ceaseless efforts to banish suffering accomplish no more than to make it change its form. It is essentially deficiency, want, care for the maintenance of life. If we succeed, which is very difficult, in removing pain in this form, it immediately assumes a thousand others, varying according to age and circumstances, such as lust, passionate love, jealousy, envy, hatred, anxiety, ambition, covetousness, sickness, &c., &c. If at last it can find entrance in no other form, it comes in the sad, grey garments of tediousness and ennui, against which we then strive in various ways. If finally we succeed in driving this away, we shall hardly do so without letting pain enter in one of its earlier forms, and the dance begin again from the beginning; for all human life is tossed backwards and forwards between pain and ennui. Depressing as this view of life is, I will draw attention, by the way, to an aspect of it from which consolation may be drawn, and perhaps even a stoical indifference to one’s own present ills may be attained. For our impatience at these arises for the most part from the fact that we regard them as brought about by a chain of causes which might easily be different. We do not generally grieve over ills which are directly necessary and quite universal; for example, the necessity of age and of death, and many daily inconveniences. It is rather the consideration of the accidental nature of the circumstances that brought some sorrow just to us, that gives it its sting. But if we have recognised that pain, as such, is inevitable and essential to life, and that nothing depends upon chance but its mere fashion, the form under which it presents itself, that thus our present sorrow fills a place that, without it, would at once be

occupied by another which now is excluded by it, and that therefore fate can affect us little in what is essential; such a reflection, if it were to become a living conviction, might produce a considerable degree of stoical equanimity, and very much lessen the anxious care for our own well-being. But, in fact, such a powerful control of reason over directly felt suffering seldom or never occurs.

Besides, through this view of the inevitableness of pain, of the supplanting of one pain by another, and the introduction of a new pain through the passing away of that which preceded it, one might be led to the paradoxical but not absurd hypothesis, that in every individual the measure of the pain essential to him was determined once for all by his nature, a measure which could neither remain empty, nor be more than filled, however much the form of the suffering might change. Thus his suffering and well-being would by no means be determined from without, but only through that measure, that natural disposition, which indeed might experience certain additions and diminutions from the physical condition at different times, but yet, on the whole, would remain the same, and would just be what is called the temperament, or, more accurately, the degree in which he might be ευκολος or δυσκολος, as Plato expresses it in the First Book of the Republic, *i.e.*, in an easy or difficult mood. This hypothesis is supported not only by the well-known experience that great suffering makes all lesser ills cease to be felt, and conversely that freedom from great suffering makes even the most trifling inconveniences torment us and put us out of humour; but experience also teaches that if a great misfortune, at the mere thought of which we shuddered, actually befalls us, as soon as we have overcome the first pain of it, our disposition remains for the most part unchanged; and, conversely, that after the attainment of some happiness we have long desired, we do not feel ourselves on the whole and permanently very much better off and agreeably situated than before. Only the moment at which these changes occur affects us with unusual strength, as deep sorrow or exulting joy, but both soon pass away, for they are based upon illusion. For they do not spring from the immediately present pleasure or pain, but only from the opening up of a new future which is anticipated in them. Only by borrowing from the future could pain or pleasure be heightened so abnormally, and consequently not enduringly. It would follow, from the hypothesis advanced, that a large part of the feeling of suffering and of well-being would be subjective and determined *a priori*, as

is the case with knowing; and we may add the following remarks as evidence in favour of it. Human cheerfulness or dejection are manifestly not determined by external circumstances, such as wealth and position, for we see at least as many glad faces among the poor as among the rich. Further, the motives which induce suicide are so very different, that we can assign no motive that is so great as to bring it about, even with great probability, in every character, and few that would be so small that the like of them had never caused it. Now although the degree of our serenity or sadness is not at all times the same, yet, in consequence of this view, we shall not attribute it to the change of outward circumstances, but to that of the inner condition, the physical state. For when an actual, though only temporary, increase of our serenity, even to the extent of joyfulness, takes place, it usually appears without any external occasion. It is true that we often see our pain arise only from some definite external relation, and are visibly oppressed and saddened by this only. Then we believe that if only this were taken away, the greatest contentment would necessarily ensue. But this is illusion. The measure of our pain and our happiness is on the whole, according to our hypothesis, subjectively determined for each point of time, and the motive for sadness is related to that, just as a blister which draws to a head all the bad humours otherwise distributed is related to the body. The pain which is at that period of time essential to our nature, and therefore cannot be shaken off, would, without the definite external cause of our suffering, be divided at a hundred points, and appear in the form of a hundred little annoyances and cares about things which we now entirely overlook, because our capacity for pain is already filled by that chief evil which has concentrated in a point all the suffering otherwise dispersed. This corresponds also to the observation that if a great and pressing care is lifted from our breast by its fortunate issue, another immediately takes its place, the whole material of which was already there before, yet could not come into consciousness as care because there was no capacity left for it, and therefore this material of care remained indistinct and unobserved in a cloudy form on the farthest horizon of consciousness. But now that there is room, this prepared material at once comes forward and occupies the throne of the reigning care of the day (πρυτανευουσα). And if it is very much lighter in its matter than the material of the care which has vanished, it knows how to blow itself out so as apparently to equal it in size, and thus, as the chief care of the day, completely fills the throne.

Excessive joy and very keen suffering always occur in the same person, for they condition each other reciprocally, and are also in common conditioned by great activity of the mind. Both are produced, as we have just seen, not by what is really present, but by the anticipation of the future. But since pain is essential to life, and its degree is also determined by the nature of the subject, sudden changes, because they are always external, cannot really alter its degree. Thus an error and delusion always lies at the foundation of immoderate joy or grief, and consequently both these excessive strainings of the mind can be avoided by knowledge. Every immoderate joy (*exultatio, insolens lætitia*) always rests on the delusion that one has found in life what can never be found there — lasting satisfaction of the harassing desires and cares, which are constantly breeding new ones. From every particular delusion of this kind one must inevitably be brought back later, and then when it vanishes must pay for it with pain as bitter as the joy its entrance caused was keen. So far, then, it is precisely like a height from which one can come down only by a fall. Therefore one ought to avoid them; and every sudden excessive grief is just a fall from some such height, the vanishing of such a delusion, and so conditioned by it. Consequently we might avoid them both if we had sufficient control over ourselves to survey things always with perfect clearness as a whole and in their connection, and steadfastly to guard against really lending them the colours which we wish they had. The principal effort of the Stoical ethics was to free the mind from all such delusion and its consequences, and to give it instead an equanimity that could not be disturbed. It is this insight that inspires Horace in the well-known ode —

"*Æquam memento rebus in arduiis*
Servare mentem, non secus in bonis
Ab insolenti temperatam
Lætitia."

For the most part, however, we close our minds against the knowledge, which may be compared to a bitter medicine, that suffering is essential to life, and therefore does not flow in upon us from without, but that every one carries about with him its perennial source in his own heart. We rather seek constantly for an external particular cause, as it were, a pretext for the pain which never leaves us, just as the free man makes himself an idol, in order to have a master. For we unweariedly strive from wish to wish; and although every satisfaction, however much it promised, when attained fails

to satisfy us, but for the most part comes presently to be an error of which we are ashamed, yet we do not see that we draw water with the sieve of the Danaides, but ever hasten to new desires.

"*Sed, dum abest quod avemus, id exsuperare videtur*
Cætera; post aliud, quum contigit illud, avemus;
Et sitis æqua tenet vitai semper hiantes." — Lucr. iii. 1095.

Thus it either goes on for ever, or, what is more rare and presupposes a certain strength of character, till we reach a wish which is not satisfied and yet cannot be given up. In that case we have, as it were, found what we sought, something that we can always blame, instead of our own nature, as the source of our suffering. And thus, although we are now at variance with our fate, we are reconciled to our existence, for the knowledge is again put far from us that suffering is essential to this existence itself, and true satisfaction impossible. The result of this form of development is a somewhat melancholy disposition, the constant endurance of a single great pain, and the contempt for all lesser sorrows or joys that proceeds from it; consequently an already nobler phenomenon than that constant seizing upon ever-new forms of illusion, which is much more common.

§ 58. All satisfaction, or what is commonly called happiness, is always really and essentially only *negative*, and never positive. It is not an original gratification coming to us of itself, but must always be the satisfaction of a wish. The wish, *i.e.*, some want, is the condition which precedes every pleasure. But with the satisfaction the wish and therefore the pleasure cease. Thus the satisfaction or the pleasing can never be more than the deliverance from a pain, from a want; for such is not only every actual, open sorrow, but every desire, the importunity of which disturbs our peace, and, indeed, the deadening ennui also that makes life a burden to us. It is, however, so hard to attain or achieve anything; difficulties and troubles without end are opposed to every purpose, and at every step hindrances accumulate. But when finally everything is overcome and attained, nothing can ever be gained but deliverance from some sorrow or desire, so that we find ourselves just in the same position as we occupied before this sorrow or desire appeared. All that is even directly given us is merely the want, *i.e.*, the pain. The satisfaction and the pleasure we can only know indirectly through the remembrance of the preceding suffering and want, which ceases with its appearance. Hence it arises that we are not properly conscious of the blessings and advantages we actually possess, nor do we prize them, but

think of them merely as a matter of course, for they gratify us only negatively by restraining suffering. Only when we have lost them do we become sensible of their value; for the want, the privation, the sorrow, is the positive, communicating itself directly to us. Thus also we are pleased by the remembrance of past need, sickness, want, and such like, because this is the only means of enjoying the present blessings. And, further, it cannot be denied that in this respect, and from this standpoint of egoism, which is the form of the will to live, the sight or the description of the sufferings of others affords us satisfaction and pleasure in precisely the way Lucretius beautifully and frankly expresses it in the beginning of the Second Book —

"*Suave, mari magno, turbantibus æquora ventis,*
E terra magnum alterius spectare laborem:
Non, quia vexari quemquam est jucunda voluptas;
Sed, quibus ipse malis careas, quia cernere suave est."

Yet we shall see farther on that this kind of pleasure, through knowledge of our own well-being obtained in this way, lies very near the source of real, positive wickedness.

That all happiness is only of a negative not a positive nature, that just on this account it cannot be lasting satisfaction and gratification, but merely delivers us from some pain or want which must be followed either by a new pain, or by languor, empty longing, and ennui; this finds support in art, that true mirror of the world and life, and especially in poetry. Every epic and dramatic poem can only represent a struggle, an effort, and fight for happiness, never enduring and complete happiness itself. It conducts its heroes through a thousand difficulties and dangers to the goal; as soon as this is reached, it hastens to let the curtain fall; for now there would remain nothing for it to do but to show that the glittering goal in which the hero expected to find happiness had only disappointed him, and that after its attainment he was no better off than before. Because a genuine enduring happiness is not possible, it cannot be the subject of art. Certainly the aim of the idyll is the description of such a happiness, but one also sees that the idyll as such cannot continue. The poet always finds that it either becomes epical in his hands, and in this case it is a very insignificant epic, made up of trifling sorrows, trifling delights, and trifling efforts — this is the commonest case — or else it becomes a merely descriptive poem, describing the beauty of nature, *i.e.*, pure knowing free from will, which certainly, as a matter of fact, is the only pure happiness, which is neither

preceded by suffering or want, nor necessarily followed by repentance, sorrow, emptiness, or satiety; but this happiness cannot fill the whole life, but is only possible at moments. What we see in poetry we find again in music; in the melodies of which we have recognised the universal expression of the inmost history of the self-conscious will, the most secret life, longing, suffering, and delight; the ebb and flow of the human heart. Melody is always a deviation from the keynote through a thousand capricious wanderings, even to the most painful discord, and then a final return to the keynote which expresses the satisfaction and appeasing of the will, but with which nothing more can then be done, and the continuance of which any longer would only be a wearisome and unmeaning monotony corresponding to ennui.

All that we intend to bring out clearly through these investigations, the impossibility of attaining lasting satisfaction and the negative nature of all happiness, finds its explanation in what is shown at the conclusion of the Second Book: that the will, of which human life, like every phenomenon, is the objectification, is a striving without aim or end. We find the stamp of this endlessness imprinted upon all the parts of its whole manifestation, from its most universal form, endless time and space, up to the most perfect of all phenomena, the life and efforts of man. We may theoretically assume three extremes of human life, and treat them as elements of actual human life. First, the powerful will, the strong passions (Radscha-Guna). It appears in great historical characters; it is described in the epic and the drama. But it can also show itself in the little world, for the size of the objects is measured here by the degree in which they influence the will, not according to their external relations. Secondly, pure knowing, the comprehension of the Ideas, conditioned by the freeing of knowledge from the service of will: the life of genius (Satwa-Guna). Thirdly and lastly, the greatest lethargy of the will, and also of the knowledge attaching to it, empty longing, life-benumbing languor (Tama-Guna). The life of the individual, far from becoming permanently fixed in one of these extremes, seldom touches any of them, and is for the most part only a weak and wavering approach to one or the other side, a needy desiring of trifling objects, constantly recurring, and so escaping ennui. It is really incredible how meaningless and void of significance when looked at from without, how dull and unenlightened by intellect when felt from within, is the course of the life of the great majority of men. It is a weary longing and complaining, a dream-like staggering

through the four ages of life to death, accompanied by a series of trivial thoughts. Such men are like clockwork, which is wound up, and goes it knows not why; and every time a man is begotten and born, the clock of human life is wound up anew, to repeat the same old piece it has played innumerable times before, passage after passage, measure after measure, with insignificant variations. Every individual, every human being and his course of life, is but another short dream of the endless spirit of nature, of the persistent will to live; is only another fleeting form, which it carelessly sketches on its infinite page, space and time; allows to remain for a time so short that it vanishes into nothing in comparison with these, and then obliterates to make new room. And yet, and here lies the serious side of life, every one of these fleeting forms, these empty fancies, must be paid for by the whole will to live, in all its activity, with many and deep sufferings, and finally with a bitter death, long feared and coming at last. This is why the sight of a corpse makes us suddenly so serious.

The life of every individual, if we survey it as a whole and in general, and only lay stress upon its most significant features, is really always a tragedy, but gone through in detail, it has the character of a comedy. For the deeds and vexations of the day, the restless irritation of the moment, the desires and fears of the week, the mishaps of every hour, are all through chance, which is ever bent upon some jest, scenes of a comedy. But the never-satisfied wishes, the frustrated efforts, the hopes unmercifully crushed by fate, the unfortunate errors of the whole life, with increasing suffering and death at the end, are always a tragedy. Thus, as if fate would add derision to the misery of our existence, our life must contain all the woes of tragedy, and yet we cannot even assert the dignity of tragic characters, but in the broad detail of life must inevitably be the foolish characters of a comedy.

But however much great and small trials may fill human life, they are not able to conceal its insufficiency to satisfy the spirit; they cannot hide the emptiness and superficiality of existence, nor exclude ennui, which is always ready to fill up every pause that care may allow. Hence it arises that the human mind, not content with the cares, anxieties, and occupations which the actual world lays upon it, creates for itself an imaginary world also in the form of a thousand different superstitions, then finds all manner of employment with this, and wastes time and strength upon it, as soon as the real world is willing to grant it the rest which it is quite incapable of

enjoying. This is accordingly most markedly the case with nations for which life is made easy by the congenial nature of the climate and the soil, most of all with the Hindus, then with the Greeks, the Romans, and later with the Italians, the Spaniards, &c. Demons, gods, and saints man creates in his own image; and to them he must then unceasingly bring offerings, prayers, temple decorations, vows and their fulfilment, pilgrimages, salutations, ornaments for their images, &c. Their service mingles everywhere with the real, and, indeed, obscures it. Every event of life is regarded as the work of these beings; the intercourse with them occupies half the time of life, constantly sustains hope, and by the charm of illusion often becomes more interesting than intercourse with real beings. It is the expression and symptom of the actual need of mankind, partly for help and support, partly for occupation and diversion; and if it often works in direct opposition to the first need, because when accidents and dangers arise valuable time and strength, instead of being directed to warding them off, are uselessly wasted on prayers and offerings; it serves the second end all the better by this imaginary converse with a visionary spirit world; and this is the by no means contemptible gain of all superstitions.

§ 59. If we have so far convinced ourselves *a priori*, by the most general consideration, by investigation of the primary and elemental features of human life, that in its whole plan it is capable of no true blessedness, but is in its very nature suffering in various forms, and throughout a state of misery, we might now awaken this conviction much more vividly within us if, proceeding more *a posteriori*, we were to turn to more definite instances, call up pictures to the fancy, and illustrate by examples the unspeakable misery which experience and history present, wherever one may look and in whatever direction one may seek. But the chapter would have no end, and would carry us far from the standpoint of the universal, which is essential to philosophy; and, moreover, such a description might easily be taken for a mere declamation on human misery, such as has often been given, and, as such, might be charged with one-sidedness, because it started from particular facts. From such a reproach and suspicion our perfectly cold and philosophical investigation of the inevitable suffering which is founded in the nature of life is free, for it starts from the universal and is conducted *a priori*. But confirmation *a posteriori* is everywhere easily obtained. Every one who has awakened from the first dream of youth, who has considered his own experience and that of others, who has studied himself in life, in the

history of the past and of his own time, and finally in the works of the great poets, will, if his judgment is not paralysed by some indelibly imprinted prejudice, certainly arrive at the conclusion that this human world is the kingdom of chance and error, which rule without mercy in great things and in small, and along with which folly and wickedness also wield the scourge. Hence it arises that everything better only struggles through with difficulty; what is noble and wise seldom attains to expression, becomes effective and claims attention, but the absurd and the perverse in the sphere of thought, the dull and tasteless in the sphere of art, the wicked and deceitful in the sphere of action, really assert a supremacy, only disturbed by short interruptions. On the other hand, everything that is excellent is always a mere exception, one case in millions, and therefore, if it presents itself in a lasting work, this, when it has outlived the enmity of its contemporaries, exists in isolation, is preserved like a meteoric stone, sprung from an order of things different from that which prevails here. But as far as the life of the individual is concerned, every biography is the history of suffering, for every life is, as a rule, a continual series of great and small misfortunes, which each one conceals as much as possible, because he knows that others can seldom feel sympathy or compassion, but almost always satisfaction at the sight of the woes from which they are themselves for the moment exempt. But perhaps at the end of life, if a man is sincere and in full possession of his faculties, he will never wish to have it to live over again, but rather than this, he will much prefer absolute annihilation. The essential content of the famous soliloquy in "Hamlet" is briefly this: Our state is so wretched that absolute annihilation would be decidedly preferable. If suicide really offered us this, so that the alternative "to be or not to be," in the full sense of the word, was placed before us, then it would be unconditionally to be chosen as "a consummation devoutly to be wished." But there is something in us which tells us that this is not the case: suicide is not the end; death is not absolute annihilation. In like manner, what was said by the father of history[71] has not since him been contradicted, that no man has ever lived who has not wished more than once that he had not to live the following day. According to this, the brevity of life, which is so constantly lamented, may be the best quality it possesses. If, finally, we should bring clearly to a man's sight the terrible sufferings and miseries to which his life is constantly exposed, he would be seized with horror; and if we were to conduct the confirmed optimist through the hospitals,

infirmaries, and surgical operating-rooms, through the prisons, torture-chambers, and slave-kennels, over battle-fields and places of execution; if we were to open to him all the dark abodes of misery, where it hides itself from the glance of cold curiosity, and, finally, allow him to glance into the starving dungeon of Ugolino, he, too, would understand at last the nature of this "best of possible worlds." For whence did Dante take the materials for his hell but from this our actual world? And yet he made a very proper hell of it. And when, on the other hand, he came to the task of describing heaven and its delights, he had an insurmountable difficulty before him, for our world affords no materials at all for this. Therefore there remained nothing for him to do but, instead of describing the joys of paradise, to repeat to us the instruction given him there by his ancestor, by Beatrice, and by various saints. But from this it is sufficiently clear what manner of world it is. Certainly human life, like all bad ware, is covered over with a false lustre: what suffers always conceals itself; on the other hand, whatever pomp or splendour any one can get, he makes a show of openly, and the more inner contentment deserts him, the more he desires to exist as fortunate in the opinion of others: to such an extent does folly go, and the opinion of others is a chief aim of the efforts of every one, although the utter nothingness of it is expressed in the fact that in almost all languages vanity, *vanitas*, originally signifies emptiness and nothingness. But under all this false show, the miseries of life can so increase — and this happens every day — that the death which hitherto has been feared above all things is eagerly seized upon. Indeed, if fate will show its whole malice, even this refuge is denied to the sufferer, and, in the hands of enraged enemies, he may remain exposed to terrible and slow tortures without remedy. In vain the sufferer then calls on his gods for help; he remains exposed to his fate without grace. But this irremediableness is only the mirror of the invincible nature of his will, of which his person is the objectivity. As little as an external power can change or suppress this will, so little can a foreign power deliver it from the miseries which proceed from the life which is the phenomenal appearance of that will. In the principal matter, as in everything else, a man is always thrown back upon himself. In vain does he make to himself gods in order to get from them by prayers and flattery what can only be accomplished by his own will-power. The Old Testament made the world and man the work of a god, but the New Testament saw that, in order to teach that holiness and salvation from the sorrows of this world can only

come from the world itself, it was necessary that this god should become man. It is and remains the will of man upon which everything depends for him. Fanatics, martyrs, saints of every faith and name, have voluntarily and gladly endured every torture, because in them the will to live had suppressed itself; and then even the slow destruction of its phenomenon was welcome to them. But I do not wish to anticipate the later exposition. For the rest, I cannot here avoid the statement that, to me, *optimism*, when it is not merely the thoughtless talk of such as harbour nothing but words under their low foreheads, appears not merely as an absurd, but also as a really *wicked* way of thinking, as a bitter mockery of the unspeakable suffering of humanity. Let no one think that Christianity is favourable to optimism; for, on the contrary, in the Gospels world and evil are used as almost synonymous.[72]

§ 60. We have now completed the two expositions it was necessary to insert; the exposition of the freedom of the will in itself together with the necessity of its phenomenon, and the exposition of its lot in the world which reflects its own nature, and upon the knowledge of which it has to assert or deny itself. Therefore we can now proceed to bring out more clearly the nature of this assertion and denial itself, which was referred to and explained in a merely general way above. This we shall do by exhibiting the conduct in which alone it finds its expression, and considering it in its inner significance.

The *assertion of the will* is the continuous willing itself, undisturbed by any knowledge, as it fills the life of man in general. For even the body of a man is the objectivity of the will, as it appears at this grade and in this individual. And thus his willing which develops itself in time is, as it were, a paraphrase of his body, an elucidation of the significance of the whole and its parts; it is another way of exhibiting the same thing-in-itself, of which the body is already the phenomenon. Therefore, instead of saying assertion of the will, we may say assertion of the body. The fundamental theme or subject of all the multifarious acts of will is the satisfaction of the wants which are inseparable from the existence of the body in health, they already have their expression in it, and may be referred to the maintenance of the individual and the propagation of the species. But indirectly the most different kinds of motives obtain in this way power over the will, and bring about the most multifarious acts of will. Each of these is only an example,

an instance, of the will which here manifests itself generally. Of what nature this example may be, what form the motive may have and impart to it, is not essential; the important point here is that something is willed in general and the degree of intensity with which it is so willed. The will can only become visible in the motives, as the eye only manifests its power of seeing in the light. The motive in general stands before the will in protean forms. It constantly promises complete satisfaction, the quenching of the thirst of will. But whenever it is attained it at once appears in another form, and thus influences the will anew, always according to the degree of the intensity of this will, and its relation to knowledge which are revealed as empirical character, in these very examples and instances.

From the first appearance of consciousness, a man finds himself a willing being, and as a rule, his knowledge remains in constant relation to his will. He first seeks to know thoroughly the objects of his desire, and then the means of attaining them. Now he knows what he has to do, and, as a rule, he does not strive after other knowledge. He moves and acts; his consciousness keeps him always working directly and actively towards the aims of his will; his thought is concerned with the choice of motives. Such is life for almost all men; they wish, they know what they wish, and they strive after it, with sufficient success to keep them from despair, and sufficient failure to keep them from ennui and its consequences. From this proceeds a certain serenity, or at least indifference, which cannot be affected by wealth or poverty; for the rich and the poor do not enjoy what they have, for this, as we have shown, acts in a purely negative way, but what they hope to attain to by their efforts. They press forward with much earnestness, and indeed with an air of importance; thus children also pursue their play. It is always an exception if such a life suffers interruption from the fact that either the æsthetic demand for contemplation or the ethical demand for renunciation proceed from a knowledge which is independent of the service of the will, and directed to the nature of the world in general. Most men are pursued by want all through life, without ever being allowed to come to their senses. On the other hand, the will is often inflamed to a degree that far transcends the assertion of the body, and then violent emotions and powerful passions show themselves, in which the individual not only asserts his own existence, but denies and seeks to suppress that of others when it stands in his way.

The maintenance of the body through its own powers is so small a degree of the assertion of will, that if it voluntarily remains at this degree, we might assume that, with the death of this body, the will also which appeared in it would be extinguished. But even the satisfaction of the sexual passions goes beyond the assertion of one's own existence, which fills so short a time, and asserts life for an indefinite time after the death of the individual. Nature, always true and consistent, here even naïve, exhibits to us openly the inner significance of the act of generation. Our own consciousness, the intensity of the impulse, teaches us that in this act the most decided *assertion of the will to live* expresses itself, pure and without further addition (any denial of other individuals); and now, as the consequence of this act, a new life appears in time and the causal series, *i.e.*, in nature; the begotten appears before the begetter, different as regards the phenomenon, but in himself, *i.e.*, according to the Idea, identical with him. Therefore it is this act through which every species of living creature binds itself to a whole and is perpetuated. Generation is, with reference to the begetter, only the expression, the symptom, of his decided assertion of the will to live: with reference to the begotten, it is not the cause of the will which appears in him, for the will in itself knows neither cause nor effect, but, like all causes, it is merely the occasional cause of the phenomenal appearance of this will at this time in this place. As thing-in-itself, the will of the begetter and that of the begotten are not different, for only the phenomenon, not the thing-in-itself, is subordinate to the *principim individuationis*. With that assertion beyond our own body and extending to the production of a new body, suffering and death, as belonging to the phenomenon of life, have also been asserted anew, and the possibility of salvation, introduced by the completest capability of knowledge, has for this time been shown to be fruitless. Here lies the profound reason of the shame connected with the process of generation. This view is mythically expressed in the dogma of Christian theology that we are all partakers in Adam's first transgression (which is clearly just the satisfaction of sexual passion), and through it are guilty of suffering and death. In this theology goes beyond the consideration of things according to the principle of sufficient reason, and recognises the Idea of man, the unity of which is re-established out of its dispersion into innumerable individuals through the bond of generation which holds them all together. Accordingly it regards every individual as on one side identical with Adam, the representative of the assertion of life, and,

so far, as subject to sin (original sin), suffering, and death; on the other side, the knowledge of the Idea of man enables it to regard every individual as identical with the saviour, the representative of the denial of the will to live, and, so far as a partaker of his sacrifice of himself, saved through his merits, and delivered from the bands of sin and death, *i.e.*, the world (Rom. v. 12-21).

Another mythical exposition of our view of sexual pleasure as the assertion of the will to live beyond the individual life, as an attainment to life which is brought about for the first time by this means, or as it were a renewed assignment of life, is the Greek myth of Proserpine, who might return from the lower world so long as she had not tasted its fruit, but who became subject to it altogether through eating the pomegranate. This meaning appears very clearly in Goethe's incomparable presentation of this myth, especially when, as soon as she has tasted the pomegranate, the invisible chorus of the Fates —

"Thou art ours!
Fasting shouldest thou return:
And the bite of the apple makes thee ours!"

It is worth noticing that Clement of Alexandria (Strom. iii. c. 15) illustrates the matter with the same image and the same expression: Οἱ μεν ευνουχισαντες ἑαυτους απο πασης ἁμαρτιας, δια την βασιλειαν, των ουρανων, μακαριοι οὑτοι εισιν, οἱ του κοσμου νηστευοντες; (*Qui se castrarunt ab omni peccato propter regnum cœlorum, ii sunt beati, a mundo jejunantes*).

The sexual impulse also proves itself the decided and strongest assertion of life by the fact that to man in a state of nature, as to the brutes, it is the final end, the highest goal of life. Self-maintenance is his first effort, and as soon as he has made provision for that, he only strives after the propagation of the species: as a merely natural being he can attempt no more. Nature also, the inner being of which is the will to live itself, impels with all her power both man and the brute towards propagation. Then it has attained its end with the individual, and is quite indifferent to its death, for, as the will to live, it cares only for the preservation of the species, the individual is nothing to it. Because the will to live expresses itself most strongly in the sexual impulse, the inner being of nature, the old poets and philosophers — Hesiod and Parmenides — said very significantly that Eros is the first, the

creator, the principle from which all things proceed. (Cf. Arist. Metaph., i. 4.) Pherecydes said: Εις ερωτα μεταβεβλησθαι τον Δια, μελλοντα δημιουργειν (*Jovem, cum mundum fabricare vellet, in cupidinem sese transformasse*). *Proclus ad Plat. Tim.*, l. iii. A complete treatment of this subject we have recently received from G. F. Schœmann, "*De Cupidine Cosmogonico*," 1852. The Mâya of the Hindus, whose work and web is the whole world of illusion, is also symbolised by love.

The genital organs are, far more than any other external member of the body, subject merely to the will, and not at all to knowledge. Indeed, the will shows itself here almost as independent of knowledge, as in those parts which, acting merely in consequence of stimuli, are subservient to vegetative life and reproduction, in which the will works blindly as in unconscious nature. For generation is only reproduction passing over to a new individual, as it were reproduction at the second power, as death is only excretion at the second power. According to all this, the genitals are properly the *focus* of will, and consequently the opposite pole of the brain, the representative of knowledge, *i.e.*, the other side of the world, the world as idea. The former are the life-sustaining principle ensuring endless life to time. In this respect they were worshipped by the Greeks in the *phallus*, and by the Hindus in the *lingam*, which are thus the symbol of the assertion of the will. Knowledge, on the other hand, affords the possibility of the suppression of willing, of salvation through freedom, of conquest and annihilation of the world.

We already considered fully at the beginning of this Fourth Book how the will to live in its assertion must regard its relation to death. We saw that death does not trouble it, because it exists as something included in life itself and belonging to it. Its opposite, generation, completely counterbalances it; and, in spite of the death of the individual, ensures and guarantees life to the will to live through all time. To express this the Hindus made the *lingam* an attribute of Siva, the god of death. We also fully explained there how he who with full consciousness occupies the standpoint of the decided assertion of life awaits death without fear. We shall therefore say nothing more about this here. Without clear consciousness most men occupy this standpoint and continually assert life. The world exists as the mirror of this assertion, with innumerable individuals in infinite time and space, in infinite suffering, between generation and death without end. Yet from no side is a complaint to be further raised about this; for the will

conducts the great tragedy and comedy at its own expense, and is also its own spectator. The world is just what it is because the will, whose manifestation it is, is what it is, because it so wills. The justification of suffering is, that in this phenomenon also the will asserts itself; and this assertion is justified and balanced by the fact that the will bears the suffering. Here we get a glimpse of *eternal justice* in the whole: we shall recognise it later more definitely and distinctly, and also in the particular. But first we must consider temporal or human justice.[73]

§ 61. It may be remembered from the Second Book that in the whole of nature, at all the grades of the objectification of will, there was a necessary and constant conflict between the individuals of all species; and in this way was expressed the inner contradiction of the will to live with itself. At the highest grade of the objectification, this phenomenon, like all others, will exhibit itself with greater distinctness, and will therefore be more easily explained. With this aim we shall next attempt to trace the source of *egoism* as the starting-point of all conflict.

We have called time and space the *principium individuationis*, because only through them and in them is multiplicity of the homogeneous possible. They are the essential forms of natural knowledge, *i.e.*, knowledge springing from the will. Therefore the will everywhere manifests itself in the multiplicity of individuals. But this multiplicity does not concern the will as thing-in-itself, but only its phenomena. The will itself is present, whole and undivided, in every one of these, and beholds around it the innumerably repeated image of its own nature; but this nature itself, the actually real, it finds directly only in its inner self. Therefore every one desires everything for himself, desires to possess, or at least to control, everything, and whatever opposes it it would like to destroy. To this is added, in the case of such beings as have knowledge, that the individual is the supporter of the knowing subject, and the knowing subject is the supporter of the world, *i.e.*, that the whole of Nature outside the knowing subject, and thus also all other individuals, exist only in its idea; it is only conscious of them as its idea, thus merely indirectly as something which is dependent on its own nature and existence; for with its consciousness the world necessarily disappears for it, *i.e.*, its being and non-being become synonymous and indistinguishable. Every knowing individual is thus in truth, and finds itself as the whole will to live, or the inner being of the world itself, and also as the complemental condition of the world as idea,

consequently as a microcosm which is of equal value with the macrocosm. Nature itself, which is everywhere and always truthful, gives him this knowledge, originally and independently of all reflection, with simple and direct certainty. Now from these two necessary properties we have given the fact may be explained that every individual, though vanishing altogether and diminished to nothing in the boundless world, yet makes itself the centre of the world, has regard for its own existence and well-being before everything else; indeed, from the natural standpoint, is ready to sacrifice everything else for this — is ready to annihilate the world in order to maintain its own self, this drop in the ocean, a little longer. This disposition is *egoism*, which is essential to everything in Nature. Yet it is just through egoism that the inner conflict of the will with itself attains to such a terrible revelation; for this egoism has its continuance and being in that opposition of the microcosm and macrocosm, or in the fact that the objectification of will has the *principium individuationis* for its form, through which the will manifests itself in the same way in innumerable individuals, and indeed entire and completely in both aspects (will and idea) in each. Thus, while each individual is given to itself directly as the whole will and the whole subject of ideas, other individuals are only given it as ideas. Therefore its own being, and the maintenance of it, is of more importance to it than that of all others together. Every one looks upon his own death as upon the end of the world, while he accepts the death of his acquaintances as a matter of comparative indifference, if he is not in some way affected by it. In the consciousness that has reached the highest grade, that of man, egoism, as well as knowledge, pain and pleasure, must have reached its highest grade also, and the conflict of individuals which is conditioned by it must appear in its most terrible form. And indeed we see this everywhere before our eyes, in small things as in great. Now we see its terrible side in the lives of great tyrants and miscreants, and in world-desolating wars; now its absurd side, in which it is the theme of comedy, and very specially appears as self-conceit and vanity. Rochefoucault understood this better than any one else, and presented it in the abstract. We see it both in the history of the world and in our own experience. But it appears most distinctly of all when any mob of men is set free from all law and order; then there shows itself at once in the distinctest form the *bellum omnium contra omnes*, which Hobbes has so admirably described in the first chapter *De Cive*. We see not only how every one tries to seize from the other what he wants himself, but

how often one will destroy the whole happiness or life of another for the sake of an insignificant addition to his own happiness. This is the highest expression of egoism, the manifestations of which in this regard are only surpassed by those of actual wickedness, which seeks, quite disinterestedly, the hurt and suffering of others, without any advantage to itself. Of this we shall speak soon. With this exhibition of the source of egoism the reader should compare the presentation of it in my prize-essay on the basis of morals, § 14.

A chief source of that suffering which we found above to be essential and inevitable to all life is, when it really appears in a definite form, that *Eris*, the conflict of all individuals, the expression of the contradiction, with which the will to live is affected in its inner self, and which attains a visible form through the *principium individuationis*. Wild-beast fights are the most cruel means of showing this directly and vividly. In this original discord lies an unquenchable source of suffering, in spite of the precautions that have been taken against it, and which we shall now consider more closely.

§ 62. It has already been explained that the first and simplest assertion of the will to live is only the assertion of one's own body, *i.e.*, the exhibition of the will through acts in time, so far as the body, in its form and design, exhibits the same will in space, and no further. This assertion shows itself as maintenance of the body, by means of the application of its own powers. To it is directly related the satisfaction of the sexual impulse; indeed this belongs to it, because the genitals belong to the body. Therefore *voluntary* renunciation of the satisfaction of that impulse, based upon no *motive*, is already a denial of the will to live, is a voluntary self-suppression of it, upon the entrance of knowledge which acts as a *quieter*. Accordingly such denial of one's own body exhibits itself as a contradiction by the will of its own phenomenon. For although here also the body objectifies in the genitals the will to perpetuate the species, yet this is not willed. Just on this account, because it is a denial or suppression of the will to live, such a renunciation is a hard and painful self-conquest; but of this later. But since the will exhibits that *self-assertion* of one's own body in innumerable individuals beside each other, it very easily extends in one individual, on account of the egoism peculiar to them all, beyond this assertion to the *denial* of the same will appearing in another individual. The will of the first breaks through the limits of the assertion of will of another, because the individual either destroys or injures this other body itself, or else because it compels the

powers of the other body to serve *its own* will, instead of the will which manifests itself in that other body. Thus if, from the will manifesting itself as another body, it withdraws the powers of this body, and so increases the power serving its own will beyond that of its own body, it consequently asserts its own will beyond its own body by means of the negation of the will appearing in another body. This breaking through the limits of the assertion of will of another has always been distinctly recognised, and its concept denoted by the word *wrong*. For both sides recognise the fact instantly, not, indeed, as we do here in distinct abstraction, but as feeling. He who suffers wrong feels the transgression into the sphere of the assertion of his own body, through the denial of it by another individual, as a direct and mental pain which is entirely separated and different from the accompanying physical suffering experienced from the act or the vexation at the loss. To the doer of wrong, on the other hand, the knowledge presents itself that he is in himself the same will which appears in that body also, and which asserts itself with such vehemence; the one phenomenon that, transgressing the limits of its own body and its powers, it extends to the denial of this very will in another phenomenon, and so, regarded as will in itself, it strives against itself by this vehemence and rends itself. Moreover, this knowledge presents itself to him instantly, not *in abstracto*, but as an obscure feeling; and this is called remorse, or, more accurately in this case, the feeling of *wrong committed*.

Wrong, the conception of which we have thus analysed in its most general and abstract form, expresses itself in the concrete most completely, peculiarly, and palpably in cannibalism. This is its most distinct and evident type, the terrible picture of the greatest conflict of the will with itself at the highest grade of its objectification, which is man. Next to this, it expresses itself most distinctly in murder; and therefore the committal of murder is followed instantly and with fearful distinctness by remorse, the abstract and dry significance of which we have just given, which inflicts a wound on our peace of mind that a lifetime cannot heal. For our horror at the murder committed, as also our shrinking from the committal of it, corresponds to that infinite clinging to life with which everything living, as phenomenon of the will to live, is penetrated. (We shall analyse this feeling which accompanies the doing of wrong and evil, in other words, the pangs of conscience, more fully later on, and raise its concept to distinctness.) Mutilation, or mere injury of another body, indeed every blow, is to be

regarded as in its nature the same as murder, and differing from it only in degree. Further, wrong shows itself in the subjugation of another individual, in forcing him into slavery, and, finally, in the seizure of another's goods, which, so far as these goods are regarded as the fruit of his labour, is just the same thing as making him a slave, and is related to this as mere injury is to murder.

For *property*, which is not taken from a man without *wrong*, can, according to our explanation of wrong, only be that which has been produced by his own powers. Therefore by taking this we really take the powers of his body from the will objectified in it, to make them subject to the will objectified in another body. For only so does the wrong-doer, by seizing, not the body of another, but a lifeless thing quite different from it, break into the sphere of the assertion of will of another person, because the powers, the work of this other body, are, as it were, incorporated and identified with this thing. It follows from this that all true, *i.e.*, moral, right of property is based simply and solely on work, as was pretty generally assumed before Kant, and is distinctly and beautifully expressed in the oldest of all codes of law: "Wise men who know the past explain that a cultured field is the property of him who cut down the wood and cleared and ploughed it, as an antelope belongs to the first hunter who mortally wounds it" (Laws of Manu, ix. 44). Kant's philosophy of law is an extraordinary concatenation of errors all leading to each other, and he bases the right of property upon first occupation. To me this is only explicable on the supposition that his powers were failing through old age. For how should the mere avowal of my will to exclude others from the use of a thing at once give me a *right* to it? Clearly such an avowal itself requires a foundation of right, instead of being one, as Kant assumes. And how would he act unjustly *in se*, *i.e.*, morally, who does not respect that claim to the sole possession of a thing which is based upon nothing but its own avowal? How should his conscience trouble him about it? For it is so clear and easy to understand that there can be absolutely no such thing as a just seizure of anything, but only a just conversion or acquired possession of it, by spending our own original powers upon it. When, by any foreign labour, however little, a thing has been cultivated, improved, kept from harm or preserved, even if this labour were only the plucking or picking up from the ground of fruit that has grown wild; the person who forcibly seizes such a thing clearly deprives the other of the result of his labour expended upon it,

makes the body of this other serve his will instead of its own, asserts his will beyond its own phenomenon to the denial of that of the other, *i.e.*, does injustice or wrong.[74] On the other hand, the mere enjoyment of a thing, without any cultivation or preservation of it from destruction, gives just as little right to it as the mere avowal of our desire for its sole possession. Therefore, though one family has hunted a district alone, even for a hundred years, but has done nothing for its improvement; if a stranger comes and desires to hunt there, it cannot prevent him from doing so without moral injustice. Thus the so-called right of preoccupation, according to which, for the mere past enjoyment of a thing, there is demanded the further recompense of the exclusive right to its future enjoyment, is morally entirely without foundation. A new-comer might with far better right reply to him who was depending upon such a right, "Just because you have so long enjoyed, it is right that others should now enjoy also." No moral right can be established to the sole possession of anything upon which labour cannot be expended, either in improving it or in preserving it from harm, unless it be through a voluntary surrender on the part of others, as a reward for other services. This, however, already presupposes a community regulated by agreement — the State. The morally established right of property, as we have deduced it above, gives, from its nature, to the owner of a thing, the same unlimited power over it which he has over his own body; and hence it follows that he can part with his possessions to others either in exchange or as a gift, and they then possess them with the same moral right as he did.

As regards the doing of wrong generally, it occurs either through violence or through craft; it matters not which as far as what is morally essential is concerned. First, in the case of murder, it is a matter of indifference whether I make use of a dagger or of poison; and the case of every bodily injury is analogous. Other cases of wrong can all be reduced to the fact that I, as the doer of wrong, compel another individual to serve my will instead of his own, to act according to my will instead of according to his own. On the path of violence I attain this end through physical causality, but on the path of craft by means of motivation, *i.e.*, by means of causality through knowledge; for I present to his will illusive motives, on account of which he follows my will, while he believes he is following his own. Since the medium in which the motives lie is knowledge, I can only accomplish this by falsifying his knowledge, and this is the *lie*. The lie always aims at

influencing another's will, not merely his knowledge, for itself and as such, but only as a means, so far as it determines his will. For my lying itself, inasmuch as it proceeds from my will, requires a motive; and only the will of another can be such a motive, not his knowledge in and for itself; for as such it can never have an influence upon *my* will, therefore it can never move it, can never be a motive of its aim. But only the willing and doing of another can be this, and his knowledge indirectly through it. This holds good not only of all lies that have manifestly sprung from self-interest, but also of those which proceed from pure wickedness, which seeks enjoyment in the painful consequences of the error into which it has led another. Indeed, mere empty boasting aims at influencing the will and action of others more or less, by increasing their respect or improving their opinion of the boaster. The mere refusal of a truth, *i.e.*, of an assertion generally, is in itself no wrong, but every imposing of a lie is certainly a wrong. He who refuses to show the strayed traveller the right road does him no wrong, but he who directs him to a false road certainly does. It follows from what has been said, that every *lie*, like every act of violence, is as such *wrong*, because as such it has for its aim the extension of the authority of my will to other individuals, and so the assertion of my will through the denial of theirs, just as much as violence has. But the most complete lie is the *broken contract*, because here all the conditions mentioned are completely and distinctly present together. For when I enter into a contract, the promised performance of the other individual is directly and confessedly the motive for my reciprocal performance. The promises were deliberately and formally exchanged. The fulfilment of the declarations made is, it is assumed, in the power of each. If the other breaks the covenant, he has deceived me, and by introducing merely illusory motives into my knowledge, he has bent my will according to his intention; he has extended the control of his will to another individual, and thus has committed a distinct wrong. On this is founded the moral lawfulness and validity of the *contract*.

Wrong through violence is not so *shameful* to the doer of it as wrong through craft; for the former arises from physical power, which under all circumstances impresses mankind; while the latter, by the use of subterfuge, betrays weakness, and lowers man at once as a physical and moral being. This is further the case because lying and deception can only succeed if he who employs them expresses at the same time horror and contempt of them

in order to win confidence, and his victory rests on the fact that men credit him with honesty which he does not possess. The deep horror which is always excited by cunning, faithlessness, and treachery rests on the fact that good faith and honesty are the bond which externally binds into a unity the will which has been broken up into the multiplicity of individuals, and thereby limits the consequences of the egoism which results from that dispersion. Faithlessness and treachery break this outward bond asunder, and thus give boundless scope to the consequences of egoism.

In the connection of our system we have found that the content of the concept of *wrong* is that quality of the conduct of an individual in which he extends the assertion of the will appearing in his own body so far that it becomes the denial of the will appearing in the bodies of others. We have also laid down, by means of very general examples, the limits at which the province of wrong begins; for we have at once defined its gradations, from the highest degree to the lowest, by means of a few leading conceptions. According to this, the concept of wrong is the original and positive, and the concept of right, which is opposed to it, is the derivative and negative; for we must keep to the concepts, and not to the words. As a matter of fact, there would be no talk of right if there were no such thing as wrong. The concept right contains merely the negation of wrong, and every action is subsumed under it which does not transgress the limit laid down above, *i.e.*, is not a denial of the will of another for the stronger assertion of our own. That limit, therefore, divides, as regards a purely *moral* definition, the whole province of possible actions into such as are wrong or right. Whenever an action does not encroach, in the way explained above, on the sphere of the assertion of will of another, denying it, it is not wrong. Therefore, for example, the refusal of help to another in great need, the quiet contemplation of the death of another from starvation while we ourselves have more than enough, is certainly cruel and fiendish, but it is not wrong; only it can be affirmed with certainty that whoever is capable of carrying unkindness and hardness to such a degree will certainly also commit every wrong whenever his wishes demand it and no compulsion prevents it.

But the conception of right as the negation of wrong finds its principal application, and no doubt its origin, in cases in which an attempted wrong by violence is warded off. This warding off cannot itself be wrong, and consequently is right, although the violence it requires, regarded in itself

and in isolation, would be wrong, and is here only justified by the motive, *i.e.*, becomes right. If an individual goes so far in the assertion of his own will that he encroaches upon the assertion of will which is essential to my person as such, and denies it, then my warding off of that encroachment is only the denial of that denial, and thus from my side is nothing more than the assertion of the will which essentially and originally appears in my body, and is already implicitly expressed by the mere appearance of this body; consequently is not wrong, but right. That is to say: I have then a right to deny that denial of another with the force necessary to overcome it, and it is easy to see that this may extend to the killing of the other individual, whose encroachment as external violence pressing upon me may be warded off by a somewhat stronger counteraction, entirely without wrong, consequently with right. For all that happens from my side lies always within the sphere of the assertion of will essential to my person as such, and already expressed by it (which is the scene of the conflict), and does not encroach on that of the other, consequently is only negation of the negation, and thus affirmation, not itself negation. Thus if the will of another denies my will, as this appears in my body and the use of its powers for its maintenance, without denial of any foreign will which observes a like limitation, I can *without wrong* compel it to desist from such denial, *i.e.*, I have so far a *right of compulsion*.

In all cases in which I have a right of compulsion, a complete right to use *violence* against another, I may, according to the circumstances, just as well oppose the violence of the other with *craft* without doing any wrong, and accordingly I have an actual *right to lie precisely so far as I have a right of compulsion*. Therefore a man acts with perfect right who assures a highway robber who is searching him that he has nothing more upon him; or, if a burglar has broken into his house by night, induces him by a lie to enter a cellar and then locks him in. A man who has been captured and carried off by robbers, for example by pirates, has the right to kill them not only by violence but also by craft, in order to regain his freedom. Thus, also, a promise is certainly not binding when it has been extorted by direct bodily violence, because he who suffers such compulsion may with full right free himself by killing, and, *a fortiori*, by deceiving his oppressor. Whoever cannot recover through force the property which has been stolen from him, commits no wrong if he can accomplish it through craft. Indeed, if some one plays with me for money he has stolen from me, I have the right to use

false dice against him, because all that I win from him already belongs to me. Whoever would deny this must still more deny the justifiableness of stratagem in war, which is just an acted lie, and is a proof of the saying of Queen Christina of Sweden, "The words of men are to be esteemed as nothing; scarcely are their deeds to be trusted." So sharply does the limit of right border upon that of wrong. For the rest, I regard it as superfluous to show that all this completely agrees with what was said above about the unlawfulness of the lie and of violence. It may also serve to explain the peculiar theory of the lie told under pressure.[75]

In accordance with what has been said, wrong and right are merely moral determinations, *i.e.*, such as are valid with regard to the consideration of human action as such, and in relation *to the inner significance of this action in itself*. This asserts itself directly in consciousness through the fact that the doing of wrong is accompanied by an inward pain, which is the merely felt consciousness of the wrong-doer of the excessive strength of the assertion of will in itself, which extends even to the denial of the manifestation of the will of another, and also the consciousness that although he is different from the person suffering wrong as far as the manifestation is concerned, yet in himself he is identical with him. The further explanation of this inner significance of all pain of conscience cannot be given till later. He who suffers wrong is, on the other hand, painfully conscious of the denial of his will, as it is expressed through the body and its natural requirements, for the satisfaction of which nature refers him to the powers of his body; and at the same time he is conscious that without doing wrong he might ward off that denial by every means unless he lacks the power. This purely moral significance is the only one which right and wrong have for men as men, not as members of the State, and which consequently remains even when man is in a state of nature without any positive law. It constitutes the basis and the content of all that has on this account been named *natural law*, though it is better called moral law, for its validity does not extend to suffering, to the external reality, but only to the action of man and the self-knowledge of his individual will which grows up in him from his action, and which is called *conscience*. It cannot, however, in a state of nature, assert itself in all cases, and outwardly upon other individuals, and prevent might from reigning instead of right. In a state of nature it depends upon every one merely to see that in every case he *does* no wrong, but by no means to see that in every case he *suffers* no wrong, for this depends on the

accident of his outward power. Therefore the concepts right and wrong, even in a state of nature, are certainly valid and by no means conventional, but there they are valid merely as *moral* concepts, for the self-knowledge of one's own will in each. They are a fixed point in the scale of the very different degrees of strength with which the will to live asserts itself in human individuals, like the freezing-point on the thermometer; the point at which the assertion of one's own will becomes the denial of the will of another, *i.e.*, specifies through wrong-doing the degree of its intensity, combined with the degree in which knowledge is involved in the *principium individuationis* (which is the form of all knowledge that is subject to the will). But whoever wants to set aside the purely moral consideration of human action, or denies it, and wishes to regard conduct merely in its outward effects and their consequences, may certainly, with Hobbes, explain right and wrong as conventional definitions arbitrarily assumed, and therefore not existing outside positive law, and we can never show him through external experience what does not belong to such experience. Hobbes himself characterises his completely empirical method of thought very remarkably by the fact that in his book "*De Principiis Geometrarum*" he denies all pure mathematics properly so called, and obstinately maintains that the point has extension and the line has breadth, and we can never show him a point without extension or a line without breadth. Thus we can just as little impart to him the *a priori* nature of mathematics as the *a priori* nature of right, because he shuts himself out from all knowledge which is not empirical.

The pure doctrine of right is thus a chapter of ethics, and is directly related only to *action*, not to *suffering*; for only the former is the expression of will, and this alone is considered by ethics. Suffering is mere occurrence. Ethics can only have regard to suffering indirectly, merely to show that what takes place merely to avoid suffering wrong is itself no infliction of wrong. The working out of this chapter of ethics would contain the precise definition of the limits to which an individual may go in the assertion of the will already objectified in his body without denying the same will as it appears in another individual; and also the actions which transgress these limits, which consequently are wrong, and therefore in their turn may be warded off without wrong. Thus our own *action* always remains the point of view of the investigation.

But the *suffering of wrong* appears as an event in outward experience, and in it is manifested, as we have said, more distinctly than anywhere else, the phenomenon of the conflict of the will to live with itself, arising from the multiplicity of individuals and from egoism, both of which are conditioned through the *principium individuationis*, which is the form of the world as idea for the knowledge of the individual. We also saw above that a very large part of the suffering essential to human life has its perennial source in that conflict of individuals.

The reason, however, which is common to all these individuals, and which enables them to know not merely the particular case, as the brutes do, but also the whole abstractly in its connection, has also taught them to discern the source of that suffering, and induced them to consider the means of diminishing it, or, when possible, of suppressing it by a common sacrifice, which is, however, more than counterbalanced by the common advantage that proceeds from it. However agreeable it is to the egoism of the individual to inflict wrong in particular cases, this has yet a necessary correlative in the suffering of wrong of another individual, to whom it is a great pain. And because the reason which surveys the whole left the one-sided point of view of the individual to which it belongs, and freed itself for the moment from its dependence upon it, it saw the pleasure of an individual in inflicting wrong always outweighed by the relatively greater pain of the other who suffered the wrong; and it found further, that because here everything was left to chance, every one had to fear that the pleasure of conveniently inflicting wrong would far more rarely fall to his lot than the pain of enduring it. From this reason recognised that both in order to diminish the suffering which is everywhere disseminated, and as far as possible to divide it equally, the best and only means was to spare all the pain of suffering wrong by renouncing all the pleasure to be obtained by inflicting it. This means is the *contract of the state* or *law*. It is easily conceived, and little by little carried out by the egoism, which, through the use of reason, proceeds methodically and forsakes its one-sided point of view. This origin of the state and of law I have indicated was already exhibited as such by Plato in the "Republic." In fact, it is the essential and only origin, determined by the nature of the matter. Moreover, in no land can the state have ever had a different origin, because it is just this mode of originating this aim that makes it a state. But it is a matter of indifference whether, in each particular nation, the condition which preceded it was that

of a horde of savages independent of each other (anarchy), or that of a horde of slaves ruled at will by the stronger (despotism). In both cases there existed as yet no state; it first arose through that common agreement; and according as that agreement is more or less free from anarchy or despotism, the state is more or less perfect. Republics tend to anarchy, monarchies to despotism, and the mean of constitutional monarchy, which was therefore devised, tends to government by factions. In order to found a perfect state, we must begin by providing beings whose nature allows them always to sacrifice their own to the public good. Till then, however, something may be attained through the existence of *one* family whose good is quite inseparable from that of the country; so that, at least in matters of importance, it can never advance the one without the other. On this rests the power and the advantage of the hereditary monarchy.

Now as ethics was concerned exclusively with right and wrong doing, and could accurately point out the limits of his action to whoever was resolved to do no wrong; politics, on the contrary, the theory of legislation, is exclusively concerned with the *suffering* of wrong, and would never trouble itself with wrong-doing at all if it were not on account of its ever-necessary correlative, the suffering of wrong, which it always keeps in view as the enemy it opposes. Indeed, if it were possible to conceive an infliction of wrong with which no suffering of wrong on the part of another was connected, the state would, consistently, by no means prohibit it. And because in ethics the will, the disposition, is the object of consideration, and the only real thing, the firm will to do wrong, which is only restrained and rendered ineffective by external might, and the actually committed wrong, are to it quite the same, and it condemns him who so wills as unjust at its tribunal. On the other hand, will and disposition, merely as such, do not concern the state at all, but only the *deed* (whether it is merely attempted or carried out), on account of its correlative, the *suffering* on the part of another. Thus for the state the deed, the event, is the only real; the disposition, the intention, is only investigated so far as the significance of the deed becomes known through it. Therefore the state will forbid no one to carry about in his thought murder and poison against another, so long as it knows certainly that the fear of the sword and the wheel will always restrain the effects of that will. The state has also by no means to eradicate the foolish purpose, the inclination to wrong-doing, the wicked disposition; but merely always to place beside every possible motive for doing a wrong

a more powerful motive for leaving it undone in the inevitable punishment that will ensue. Therefore the criminal code is as complete a register as possible of motives against every criminal action that can possibly be imagined — both *in abstracto*, in order to make any case that occurs an application *in concreto*. Politics or legislation will therefore for this end borrow from that chapter of ethics which is the doctrine of right, and which, besides the inner significance of right and wrong, determines the exact limits between them. Yet it will only do so for the purpose of making use of its reverse side, and regarding all the limits which ethics lays down as not to be transgressed, if we are to avoid *doing* wrong, from the other side, as the limits which we must not allow others to transgress if we do not wish to *suffer* wrong, and from which we have therefore a *right* to drive others back. Therefore these limits are, as much as possible, from the passive side, barricaded by laws. It is evident that as an historian has very wittily been called an inverted prophet, the professor of law is an inverted moralist, and therefore law itself, in its proper sense, *i.e.*, the doctrine of the *right*, which we ought to maintain, is inverted ethics in that chapter of it in which the rights are laid down which we ought not to violate. The concept of wrong and its negation, that of right, which is originally *ethical*, becomes *juridical* by the transference of the starting-point from the active to the passive side, and thus by inversion. This, as well as Kant's theory of law, which very falsely deduces the institution of the state as a moral duty from his categorical imperative, has, even in the most recent times, repeatedly occasioned the very extraordinary error that the state is an institution for furthering morality; that it arises from the endeavour after this, and is, consequently, directed against egoism. As if the inward disposition, to which alone morality or immorality belongs, the externally free will, would allow itself to be modified from without and changed by influences exerted upon it! Still more perverse is the theory that the state is the condition of freedom in the moral sense, and in this way the condition of morality; for freedom lies beyond the phenomenon, and indeed beyond human arrangements. The state is, as we have said, so little directed against egoism in general and as such, that, on the contrary, it has sprung from egoism and exists only in its service — an egoism that well understands itself, proceeds methodically and forsakes the one-sided for the universal point of view, and so by addition is the common egoism of all. The state is thus instituted under the correct presupposition that pure morality, *i.e.*, right action from

moral grounds, is not to be expected; if this were not the case, it would itself be superfluous. Thus the state, which aims at well-being, is by no means directed against egoism, but only against the disadvantageous consequences which arise from the multiplicity of egoistic individuals, and reciprocally affect them all and disturb their well-being. Therefore it was already said by Aristotle (De. Rep. iii.): Τελος μεν ουν πολεως το ευ ζην; τουτο δε εστιν το ζῃν ευδαιμονως και καλως (*Finis civitatis est bene vivere, hoc autem est beate et pulchre vivere*). Hobbes also has accurately and excellently expounded this origin and end of the state; and that old first principle of all state policy, *salus publica prima lex esto*, indicates the same thing. If the state completely attains its end, it will produce the same outward result as if perfect justice of disposition prevailed everywhere. But the inner nature and origin of both phenomena will be the converse. Thus in the second case it would be that no one wished to *do* wrong, and in the first that no one wished to *suffer* wrong, and the means appropriate to this end had been fully employed. Thus the same line may be drawn from opposite directions, and a beast of prey with a muzzle is as harmless as a graminivorous animal. But beyond this point the state cannot go. It cannot exhibit a phenomenon such as would spring from universal mutual well-wishing and love. For just as we found that from its nature it would not forbid the doing of a wrong which involved no corresponding suffering of wrong on the part of another, and prohibits all wrong-doing only because this is impossible; so conversely, in accordance with its tendency towards the well-being of all, it would very gladly take care that every benevolent action and work of human love should be *experienced*, if it were not that these also have an inevitable correlative in the *performance* of acts of benevolence and works of love, and every member of the state would wish to assume the passive and none the active rôle, and there would be no reason for exacting the latter from one member of the state rather than from another. Accordingly only the negative, which is just the *right*, not the positive, which has been comprehended under the name of obligations of love, or, less completely, duties, *can be exacted by force*.

Legislation, as we have said, borrows the pure philosophy of right, or the doctrine of the nature and limits of right and wrong, from ethics, in order to apply it from the reverse side to its own ends, which are different from those of ethics, and to institute positive legislation and the means of supporting it, *i.e.*, the state, in accordance with it. Positive legislation is thus

the inverted application of the purely moral doctrine of right. This application may be made with reference to the peculiar relations and circumstances of a particular people. But only if the positive legislation is, in essential matters, throughout determined in accordance with the guidance of the pure theory of right, and for each of its propositions a ground can be established in the pure theory of right, is the legislation which has arisen a *positive right* and the state a community *based upon right*, a *state* in the proper meaning of the word, a morally permissible, not immoral institution. Otherwise the positive legislation is, on the contrary, the establishment of a *positive wrong*; it is itself an openly avowed enforced wrong. Such is every despotism, the constitution of most Mohammedan kingdoms; and indeed various parts of many constitutions are also of this kind; for example, serfdom, vassalage, and many such institutions. The pure theory of right or natural right — better, moral right — though always reversed, lies at the foundation of every just positive legislation, as pure mathematics lies at the foundation of every branch of applied mathematics. The most important points of the doctrine of right, as philosophy has to supply it for that end to legislation, are the following: 1. The explanation of the inner and real significance both of the origin of the conceptions of wrong and right, and of their application and position in ethics. 2. The deduction of the law of property. 3. The deduction of the moral validity of contracts; for this is the moral basis of the contract of the state. 4. The explanation of the origin and the aim of the state, of the relation of this aim to ethics, and of the intentional transference of the ethical doctrine of right, by reversing it, to legislation, in consequence of this relation. 5. The deduction of the right of punishment. The remaining content of the doctrine of right is mere application of these principles, mere accurate definition of the limits of right and wrong for all possible relations of life, which are consequently united and distributed under certain points of view and titles. In these special doctrines the books which treat of pure law are fairly at one; it is only in the principles that they differ much, for these are always connected with some philosophical system. In connection with our system, we have explained the first four of these principal points shortly and generally, yet definitely and distinctly, and it remains for us to speak in the same way of the right of punishment.

Kant makes the fundamentally false assertion that apart from the state there would be no complete right of property. It follows from our deduction,

as given above, that even in a state of nature there is property with complete natural, *i.e.*, moral right, which cannot be injured without wrong, but may without wrong be defended to the uttermost. On the other hand, it is certain that apart from the state there is no right of punishment. All right to punish is based upon the positive law alone, which *before* the offence has determined a punishment for it, the threat of which, as a counter-motive, is intended to outweigh all possible motives for the offence. This positive law is to be regarded as sanctioned and recognised by all the members of the state. It is thus based upon a common contract which the members of the state are in duty bound to fulfil, and thus, on the one hand, to inflict the punishment, and, on the other hand, to endure it; thus the endurance of the punishment may with right be enforced. Consequently the immediate *end of punishment* is, in the particular case, *the fulfilment of the law as a contract*. But the one end of the *law* is *deterrence* from the infringement of the rights of others. For, in order that every one may be protected from suffering wrong, men have combined to form a state, have renounced the doing of wrong, and assumed the task of maintaining the state. Thus the law and the fulfilment of it, the punishment, are essentially directed to the *future*, not to the *past*. This distinguishes *punishment* from *revenge*; for the motives which instigate the latter are solely concerned with what has happened, and thus with the past as such. All requital of wrong by the infliction of pain, without any aim for the future, is revenge, and can have no other end than consolation for the suffering one has borne by the sight of the suffering one has inflicted upon another. This is wickedness and cruelty, and cannot be morally justified. Wrong which some one has inflicted upon me by no means entitles me to inflict wrong upon him. The requital of evil with evil without further intention is neither morally nor otherwise through any rational ground to be justified, and the *jus talionis* set up as the absolute, final principle of the right of punishment, is meaningless. Therefore Kant's theory of punishment as mere requital for requital's sake is a completely groundless and perverse view. Yet it is always appearing in the writings of many jurists, under all kinds of lofty phrases, which amount to nothing but empty words, as: Through the punishment the crime is expiated or neutralised and abolished, and many such. But no man has the right to set himself up as a purely moral judge and requiter, and punish the misdeeds of another with pains which he inflicts upon him, and so to impose penance upon him for his sins. Nay, this would rather be the most presumptuous

arrogance; and therefore the Bible says, “Vengeance is mine; I will repay, saith the Lord.” But man has the right to care for the safety of society; and this can only be done by interdicting all actions which are denoted by the word “criminal,” in order to prevent them by means of counter-motives, which are the threatened punishments. And this threat can only be made effective by carrying it out when a case occurs in spite of it. Accordingly that the end of punishment, or more accurately of penal law, is the deterrence from crime, is a truth so generally recognised and indeed self-evident, that in England it is expressed in the very old form of indictment which is still served by the counsel for the Crown in criminal actions, for it concludes with the words, “If this be proved, you, the said N. N., ought to be punished with pains of law, to deter others from the like crimes in all time coming.” If a prince desires to extend mercy to a criminal who has justly been condemned, his Ministers will represent to him that, if he does, this crime will soon be repeated. An end for the future distinguishes punishment from revenge, and punishment only has this end when it is inflicted *in fulfilment of a law*. It thus announces itself as inevitable in every future case, and thus the law obtains the power to deter, in which its end really consists. Now here a Kantian would inevitably reply that certainly according to this view the punished criminal would be used “merely as a means.” This proposition, so unweariedly repeated by all the Kantians, “Man must always be treated as an end, never as a means,” certainly sounds significant, and is therefore a very suitable proposition for those who like to have a formula which saves them all further thought; but looked at in the light, it is an exceedingly vague, indefinite assertion, which reaches its aim quite indirectly, requires to be explained, defined, and modified in every case of its application, and, if taken generally, is insufficient, meagre, and moreover problematical. The murderer who has been condemned to the punishment of death according to law must now, at any rate, and with complete right, be used as a mere means. For public security, the chief end of the state, is disturbed by him; indeed it is abolished if the law is not carried out. The murderer, his life, his person, must now be the means of fulfilling the law, and thereby of re-establishing the public security. And he is made such a means with perfect right, in fulfilment of the contract of the state, which was entered into by him because he was a citizen, and in accordance with which, in order to enjoy security for his life, freedom, and

property, he has pledged his life, his freedom, and his property for the security of all, which pledge has now been forfeited.

This theory of punishment which we have established, the theory which is directly supported by sound reason, is certainly in the main no new thought; but it is a thought which was almost supplanted by new errors, and therefore it was necessary to exhibit it as distinctly as possible. The same thing is in its essence contained in what Puffendorf says on the subject, "*De Officio Hominis et Civis*" (Bk. ii. chap. 12). Hobbes also agrees with it, "Leviathan" (chaps. 15-28). In our own day Feurbach is well known to have maintained it. Indeed, it occurs even in the utterances of the ancient philosophers. Plato expresses it clearly in the "Protagoras" (p. 114, edit. Bip.), also in the "Gorgias" (p. 168), and lastly in the eleventh book of the "Laws" (p. 165). Seneca expresses Plato's opinion and the theory of all punishment in the short sentence, "*Nemo prudens punit, quia peccatum est; sed ne peccetur*" (De Ira, i. 16).

Thus we have come to recognise in the state the means by which egoism endowed with reason seeks to escape from its own evil consequences which turn against itself, and now each promotes the well-being of all because he sees that his own well-being is involved in it. If the state attained its end completely, then to a certain extent something approaching to an Utopia might finally, by the removal of all kinds of evil, be brought about. For by the human powers united in it, it is able to make the rest of nature more and more serviceable. But as yet the state has always remained very far from this goal. And even if it attained to it, innumerable evils essential to all life would still keep it in suffering; and finally, if they were all removed, ennui would at once occupy every place they left. And besides, the strife of individuals is never completely abolished by the state, for it vexes in trifles when it is prohibited in greater things. Finally, Eris, happily expelled from within, turns to what is without; as the conflict of individuals, she is banished by the institution of the state; but she reappears from without as the war of nations, and now demands in bulk and at once, as an accumulated debt, the bloody sacrifice which by wise precautions has been denied her in the particular. And even supposing that all this were finally overcome and removed, by wisdom founded on the experience of thousands of years, at the end the result would be the actual over-population of the whole planet, the terrible evil of which only a bold imagination can now realise.[76]

§ 63. We have recognised *temporal justice*, which has its seat in the state, as requiting and punishing, and have seen that this only becomes justice through a reference to the *future*. For without this reference all punishing and requiting would be an outrage without justification, and indeed merely the addition of another evil to that which has already occurred, without meaning or significance. But it is quite otherwise with *eternal justice*, which was referred to before, and which rules not the state but the world, is not dependent upon human institutions, is not subject to chance and deception, is not uncertain, wavering, and erring, but infallible, fixed, and sure. The conception of requital implies that of time; therefore *eternal justice* cannot be requital. Thus it cannot, like temporal justice, admit of respite and delay, and require time in order to triumph, equalising the evil deed by the evil consequences only by means of time. The punishment must here be so bound up with the offence that both are one.

Δοκειτε πηδᾳν τʹ αδικηματʹ εις θεους
Πτεροισι, κἁπειτʹ εν Διος δελτου πτυχαις
Γραφειν τινʹ αυτα, Ζηνα δʹ εισορωντα νιν
Θνητοις δικαζειν? Ουδʹ ὁ παρ ουρανος,
Διος γραφοντος ταρ βροτων ἁμαρτιας,
Εξαρκεσειεν, ουδʹ εκεινος αν σκοπων
Πεμπειν ἑκαστῳ ζημιαν; αλλʹ ἡ Δικη
Ενταυθα που εστιν εγγυς, ει βουλεσθʹ ὁρᾳν.
Eurip. ap. Stob. Ecl., i. c. 4.
(“Volare pennis scelera ad ætherias domus
Putatis, illic in Jovis tabularia
Scripto referri; tum Jovem lectis super
Sententiam proferre? — sed mortalium
Facinora cœli, quantaquanta est, regia
Nequit tenere: nec legendis Juppiter
Et puniendis par est. Est tamen ultio,
Et, si intuemur, illa nos habitat prope.”)

Now that such an eternal justice really lies in the nature of the world will soon become completely evident to whoever has grasped the whole of the thought which we have hitherto been developing.

The world, in all the multiplicity of its parts and forms, is the manifestation, the objectivity, of the one will to live. Existence itself, and the kind of existence, both as a collective whole and in every part, proceeds from the will alone. The will is free, the will is almighty. The will appears in everything, just as it determines itself in itself and outside time. The world is only the mirror of this willing; and all finitude, all suffering, all miseries, which it contains, belong to the expression of that which the will wills, are as they are because the will so wills. Accordingly with perfect right every being supports existence in general, and also the existence of its species and its peculiar individuality, entirely as it is and in circumstances as they are, in a world such as it is, swayed by chance and error, transient, ephemeral, and constantly suffering; and in all that it experiences, or indeed can experience, it always gets its due. For the will belongs to it; and as the will is, so is the world. Only this world itself can bear the responsibility of its own existence and nature — no other; for by what means could another have assumed it? Do we desire to know what men, morally considered, are worth as a whole and in general, we have only to consider their fate as a whole and in general. This is want, wretchedness, affliction, misery, and death. Eternal justice reigns; if they were not, as a whole, worthless, their fate, as a whole, would not be so sad. In this sense we may say, the world itself is the judgment of the world. If we could lay all the misery of the world in one scale of the balance, and all the guilt of the world in the other, the needle would certainly point to the centre.

Certainly, however, the world does not exhibit itself to the knowledge of the individual as such, developed for the service of the will, as it finally reveals itself to the inquirer as the objectivity of the one and only will to live, which he himself is. But the sight of the uncultured individual is clouded, as the Hindus say, by the veil of Mâyâ. He sees not the thing-in-itself but the phenomenon in time and space, the *principium individuationis*, and in the other forms of the principle of sufficient reason. And in this form of his limited knowledge he sees not the inner nature of things, which is one, but its phenomena as separated, disunited, innumerable, very different, and indeed opposed. For to him pleasure appears as one thing and pain as quite another thing: one man as a tormentor and a murderer, another as a martyr and a victim; wickedness as one thing and evil as another. He sees one man live in joy, abundance, and pleasure, and even at his door another die miserably of want and cold. Then he asks, Where is the retribution? And

he himself, in the vehement, pressure of will which is his origin and his nature, seizes upon the pleasures and enjoyments of life, firmly embraces them, and knows not that by this very act of his will he seizes and hugs all those pains and sorrows at the sight of which he shudders. He sees the ills and he sees the wickedness in the world, but far from knowing that both of these are but different sides of the manifestation of the one will to live, he regards them as very different, and indeed quite opposed, and often seeks to escape by wickedness, *i.e.*, by causing the suffering of another, from ills, from the suffering of his own individuality, for he is involved in the *principium individuationis*, deluded by the veil of Mâyâ. Just as a sailor sits in a boat trusting to his frail barque in a stormy sea, unbounded in every direction, rising and falling with the howling mountainous waves; so in the midst of a world of sorrows the individual man sits quietly, supported by and trusting to the *principium individuationis*, or the way in which the individual knows things as phenomena. The boundless world, everywhere full of suffering in the infinite past, in the infinite future, is strange to him, indeed is to him but a fable; his ephemeral person, his extensionless present, his momentary satisfaction, this alone has reality for him; and he does all to maintain this, so long as his eyes are not opened by a better knowledge. Till then, there lives only in the inmost depths of his consciousness a very obscure presentiment that all that is after all not really so strange to him, but has a connection with him, from which the *principium individuationis* cannot protect him. From this presentiment arises that ineradicable *awe* common to all men (and indeed perhaps even to the most sensible of the brutes) which suddenly seizes them if by any chance they become puzzled about the *principium individuationis*, because the principle of sufficient reason in some one of its forms seems to admit of an exception. For example, if it seems as if some change took place without a cause, or some one who is dead appears again, or if in any other way the past or the future becomes present or the distant becomes near. The fearful terror at anything of the kind is founded on the fact that they suddenly become puzzled about the forms of knowledge of the phenomenon, which alone separate their own individuality from the rest of the world. But even this separation lies only in the phenomenon, and not in the thing-in-itself; and on this rests eternal justice. In fact, all temporal happiness stands, and all prudence proceeds, upon ground that is undermined. They defend the person from accidents and supply its pleasures; but the person is merely phenomenon, and its

difference from other individuals, and exemption from the sufferings which they endure, rests merely in the form of the phenomenon, the *principium individuationis*. According to the true nature of things, every one has all the suffering of the world as his own, and indeed has to regard all merely possible suffering as for him actual, so long as he is the fixed will to live, *i.e.*, asserts life with all his power. For the knowledge that sees through the *principium individuationis*, a happy life in time, the gift of chance or won by prudence, amid the sorrows of innumerable others, is only the dream of a beggar in which he is a king, but from which he must awake and learn from experience that only a fleeting illusion had separated him from the suffering of his life.

Eternal justice withdraws itself from the vision that is involved in the knowledge which follows the principle of sufficient reason in the *principium individuationis*; such vision misses it altogether unless it vindicates it in some way by fictions. It sees the bad, after misdeeds and cruelties of every kind, live in happiness and leave the world unpunished. It sees the oppressed drag out a life full of suffering to the end without an avenger, a requiter appearing. But that man only will grasp and comprehend eternal justice who raises himself above the knowledge that proceeds under the guidance of the principle of sufficient reason, bound to the particular thing, and recognises the Ideas, sees through the *principium individuationis*, and becomes conscious that the forms of the phenomenon do not apply to the thing-in-itself. Moreover, he alone, by virtue of the same knowledge, can understand the true nature of virtue, as it will soon disclose itself to us in connection with the present inquiry, although for the practice of virtue this knowledge in the abstract is by no means demanded. Thus it becomes clear to whoever has attained to the knowledge referred to, that because the will is the in-itself of all phenomena, the misery which is awarded to others and that which he experiences himself, the bad and the evil, always concerns only that one inner being which is everywhere the same, although the phenomena in which the one and the other exhibits itself exist as quite different individuals, and are widely separated by time and space. He sees that the difference between him who inflicts the suffering and him who must bear it is only the phenomenon, and does not concern the thing-in-itself, for this is the will living in both, which here, deceived by the knowledge which is bound to its service, does not recognise itself, and seeking an increased happiness in *one* of its phenomena, produces great

suffering in *another*, and thus, in the pressure of excitement, buries its teeth in its own flesh, not knowing that it always injures only itself, revealing in this form, through the medium of individuality, the conflict with itself which it bears in its inner nature. The inflicter of suffering and the sufferer are one. The former errs in that he believes he is not a partaker in the suffering; the latter, in that he believes he is not a partaker in the guilt. If the eyes of both were opened, the inflicter of suffering would see that he lives in all that suffers pain in the wide world, and which, if endowed with reason, in vain asks why it was called into existence for such great suffering, its desert of which it does not understand. And the sufferer would see that all the wickedness which is or ever was committed in the world proceeds from that will which constitutes *his* own nature also, appears also in *him*, and that through this phenomenon and its assertion he has taken upon himself all the sufferings which proceed from such a will and bears them as his due, so long as he is this will. From this knowledge speaks the profound poet Calderon in "Life a Dream" —

"Pues el delito mayor
Del hombre es haber nacido."
("For the greatest crime of man
Is that he ever was born.")

Why should it not be a crime, since, according to an eternal law, death follows upon it? Calderon has merely expressed in these lines the Christian dogma of original sin.

The living knowledge of eternal justice, of the balance that inseparably binds together the *malum culpæ* with the *malum pœnæ*, demands the complete transcending of individuality and the principle of its possibility. Therefore it will always remain unattainable to the majority of men, as will also be the case with the pure and distinct knowledge of the nature of all virtue, which is akin to it, and which we are about to explain. Accordingly the wise ancestors of the Hindu people have directly expressed it in the Vedas, which are only allowed to the three regenerate castes, or in their esoteric teaching, so far at any rate as conception and language comprehend it, and their method of exposition, which always remains pictorial and even rhapsodical, admits; but in the religion of the people, or exoteric teaching, they only communicate it by means of myths. The direct exposition we find in the Vedas, the fruit of the highest human knowledge and wisdom, the kernel of which has at last reached us in the Upanishads as the greatest gift

of this century. It is expressed in various ways, but especially by making all the beings in the world, living and lifeless, pass successively before the view of the student, and pronouncing over every one of them that word which has become a formula, and as such has been called the Mahavakya: Tatoumes, — more correctly, Tat twam asi, — which means, “This thou art.”[77] But for the people, that great truth, so far as in their limited condition they could comprehend it, was translated into the form of knowledge which follows the principle of sufficient reason. This form of knowledge is indeed, from its nature, quite incapable of apprehending that truth pure and in itself, and even stands in contradiction to it, yet in the form of a myth it received a substitute for it which was sufficient as a guide for conduct. For the myth enables the method of knowledge, in accordance with the principle of sufficient reason, to comprehend by figurative representation the ethical significance of conduct, which itself is ever foreign to it. This is the aim of all systems of religion, for as a whole they are the mythical clothing of the truth which is unattainable to the uncultured human intellect. In this sense this myth might, in Kant’s language, be called a postulate of the practical reason; but regarded as such, it has the great advantage that it contains absolutely no elements but such as lie before our eyes in the course of actual experience, and can therefore support all its conceptions with perceptions. What is here referred to is the myth of the transmigration of souls. It teaches that all sufferings which in life one inflicts upon other beings must be expiated in a subsequent life in this world, through precisely the same sufferings; and this extends so far, that he who only kills a brute must, some time in endless time, be born as the same kind of brute and suffer the same death. It teaches that wicked conduct involves a future life in this world in suffering and despised creatures, and, accordingly, that one will then be born again in lower castes, or as a woman, or as a brute, as Pariah or Tschandala, as a leper, or as a crocodile, and so forth. All the pains which the myth threatens it supports with perceptions from actual life, through suffering creatures which do not know how they have merited their misery, and it does not require to call in the assistance of any other hell. As a reward, on the other hand, it promises re-birth in better, nobler forms, as Brahmans, wise men, or saints. The highest reward, which awaits the noblest deeds and the completest resignation, which is also given to the woman who in seven successive lives has voluntarily died on the funeral pile of her husband, and not less to the man whose pure mouth has never

uttered a single lie, — this reward the myth can only express negatively in the language of this world by the promise, which is so often repeated, that they shall never be born again, *Non adsumes iterum existentiam apparentem*; or, as the Buddhists, who recognise neither Vedas nor castes, express it, "Thou shalt attain to Nirvâna," *i.e.*, to a state in which four things no longer exist — birth, age, sickness, and death.

Never has a myth entered, and never will one enter, more closely into the philosophical truth which is attainable to so few than this primitive doctrine of the noblest and most ancient nation. Broken up as this nation now is into many parts, this myth yet reigns as the universal belief of the people, and has the most decided influence upon life to-day, as four thousand years ago. Therefore Pythagoras and Plato have seized with admiration on that *ne plus ultra* of mythical representation, received it from India or Egypt, honoured it, made use of it, and, we know not how far, even believed it. We, on the contrary, now send the Brahmans English clergymen and evangelical linen-weavers to set them right out of sympathy, and to show them that they are created out of nothing, and ought thankfully to rejoice in the fact. But it is just the same as if we fired a bullet against a cliff. In India our religions will never take root. The ancient wisdom of the human race will not be displaced by what happened in Galilee. On the contrary, Indian philosophy streams back to Europe, and will produce a fundamental change in our knowledge and thought.

§ 64. From our exposition of eternal justice, which is not mythical but philosophical, we will now proceed to the kindred investigation of the ethical significance of conduct and of conscience, which is the merely felt knowledge of that significance. But first I wish at this point to draw attention to two peculiarities of human nature, that might help to make clear how the nature of that eternal justice, and the unity and identity of the will in all its phenomena upon which it rests, is known to every one, at least as an obscure feeling.

When a bad deed has been done, it affords satisfaction not only to the sufferer, who for the most part feels the desire of revenge, but also to the perfectly indifferent spectator, to see that he who caused another pain suffers himself a like measure of pain; and this quite independently of the end which we have shown the state has in view in punishment, and which is the foundation of penal law. It seems to me that what expresses itself here is nothing but the consciousness of that eternal justice, which is, nevertheless,

at once misunderstood and falsified by the unenlightened mind, for, involved in the *principium individuationis*, it produces an amphiboly of the concepts and demands from the phenomenon what only belongs to the thing in itself. It does not see how far in themselves the offender and the offended are one, and that it is the same being which, not recognising itself in its own manifestation, bears both the pain and the guilt, but it desires rather to see the pain also in the particular individual to whom the guilt belongs. Therefore, most persons would demand that a man who had a very high degree of wickedness which might yet occur in many others, only not matched with other qualities such as are found in him, a man who also far surpassed others by extraordinary intellectual powers, and who inflicted unspeakable sufferings upon millions of others — for example, as a conqueror, — most persons, I say, would demand that such a man should at some time and in some place expiate all these sufferings by a like amount of pain; for they do not recognise how in themselves the inflicter of suffering and the sufferers are one, and that it is the same will through which the latter exist and live which also appears in the former, and just through him attains to a distinct revelation of its nature, and which likewise suffers both in the oppressed and the oppressor; and indeed in the latter in a greater measure, as the consciousness has attained a higher degree of clearness and distinctness and the will has greater vehemence. But that the deeper knowledge, which is no longer involved in the *principium individuationis*, from which all virtue and nobleness proceed, no longer retains the disposition which demands requital, is shown by the Christian ethics, which absolutely forbids all requital of evil with evil, and allows eternal justice to proceed in the sphere of the thing-in-itself, which is different from that of the phenomenon. (“Vengeance is mine; I will repay, saith the Lord,” — Rom. xii. 19.)

A much more striking, but also a much rarer, characteristic of human nature, which expresses that desire to draw eternal justice into the province of experience, *i.e.*, of individuality, and at the same time indicates a felt consciousness that, as I have expressed it above, the will to live conducts at its own cost the great tragedy and comedy, and that the same one will lives in all manifestations, — such a characteristic, I say, is the following. We sometimes see a man so deeply moved by a great injury which he has experienced, or, it may be, only witnessed, that he deliberately and irretrievably stakes his own life in order to take vengeance on the perpetrator of that wrong. We see him seek for some mighty oppressor through long years, murder him at last, and then himself die on the scaffold, as he had foreseen, and often, it may be, did not seek to avoid, for his life had value for him only as a means of vengeance. We find examples of this especially among the Spaniards.[78] If, now, we consider the spirit of that desire for retribution carefully, we find that it is very different from common revenge, which seeks to mitigate the suffering, endured by the sight of the suffering inflicted; indeed, we find that what it aims at deserves to be called, not so much revenge as punishment. For in it there really lies the intention of an effect upon the future through the example, and that without any selfish aim, either for the avenging person, for it costs him his life, or for a society which secures its own safety by laws. For that punishment is carried out by individuals, not by the state, nor is it in fulfilment of a law, but, on the contrary, always concerns a deed which the state either would not or could not punish, and the punishment of which it condemns. It seems to me that the indignation which carries such a man so far beyond the limits of all self-love springs from the deepest consciousness that he himself is the whole will to live, which appears in all beings through all time, and that therefore the most distant future belongs to him just as the present, and cannot be indifferent to him. Asserting this will, he yet desires that in the drama which represents its nature no such fearful wrong shall ever appear again, and wishes to frighten ever future wrong-doer by the example of a vengeance against which there is no means of defence, since the avenger is not deterred by the fear of death. The will to live, though still asserting itself, does not here depend any longer upon the particular phenomenon, the individual, but comprehends the Idea of man, and wishes to keep its manifestation pure from such a fearful and shocking wrong. It is a rare, very significant, and even sublime trait of character through which

the individual sacrifices himself by striving to make himself the arm of eternal justice, of the true nature of which he is yet ignorant.

§ 65. In all the preceding investigations of human action, we have been leading up to the final investigation, and have to a considerable extent lightened the task of raising to abstract and philosophical clearness, and exhibiting as a branch of our central thought that special ethical significance of action which in life is with perfect understanding denoted by the words *good* and *bad*.

First, however, I wish to trace back to their real meaning those conceptions of *good* and *bad* which have been treated by the philosophical writers of the day, very extraordinarily, as simple conceptions, and thus incapable of analysis; so that the reader may not remain involved in the senseless delusion that they contain more than is actually the case, and express in and for themselves all that is here necessary. I am in a position to do this because in ethics I am no more disposed to take refuge behind the word *good* than formerly behind the words *beautiful* and *true*, in order that by the adding a "ness," which at the present day is supposed to have a special σεμνοτης, and therefore to be of assistance in various cases, and by assuming an air of solemnity, I might induce the belief that by uttering three such words I had done more than denote three very wide and abstract, and consequently empty conceptions, of very different origin and significance. Who is there, indeed, who has made himself acquainted with the books of our own day to whom these three words, admirable as are the things to which they originally refer, have not become an aversion after he has seen for the thousandth time how those who are least capable of thinking believe that they have only to utter these three words with open mouth and the air of an intelligent sheep, in order to have spoken the greatest wisdom?

The explanation of the concept *true* has already been given in the essay on the principle of sufficient reason, chap. v. § 29 *et seq.* The content of the concept *beautiful* found for the first time its proper explanation through the whole of the Third Book of the present work. We now wish to discover the significance of the concept *good*, which can be done with very little trouble. This concept is essentially relative, and signifies *the conformity of an object to any definite effort of the will*. Accordingly everything that corresponds to the will in any of its expressions and fulfils its end is thought through the concept *good*, however different such things may be in other respects. Thus we speak of good eating, good roads, good weather, good weapons, good

omens, and so on; in short, we call everything good that is just as we wish it to be; and therefore that may be good in the eyes of one man which is just the reverse in those of another. The conception of the good divides itself into two sub-species — that of the direct and present satisfaction of any volition, and that of its indirect satisfaction which has reference to the future, *i.e.*, the agreeable and the useful. The conception of the opposite, so long as we are speaking of unconscious existence, is expressed by the word *bad*, more rarely and abstractly by the word *evil*, which thus denotes everything that does not correspond to any effort of the will. Like all other things that can come into relation to the will, men who are favourable to the ends which happen to be desired, who further and befriend them, are called good, in the same sense, and always with that relative limitation, which shows itself, for example, in the expression, "I find this good, but you don't." Those, however, who are naturally disposed not to hinder the endeavours of others, but rather to assist them, and who are thus consistently helpful, benevolent, friendly, and charitable, are called *good* men, on account of this relation of their conduct to the will of others in general. In the case of conscious beings (brutes and men) the contrary conception is denoted in German, and, within the last hundred years or so, in French also, by a different word from that which is used in speaking of unconscious existence; in German, *böse*; in French, *méchant*; while in almost all other languages this distinction does not exist; and κακος, *malus*, *cattivo*, *bad*, are used of men, as of lifeless things, which are opposed to the ends of a definite individual will. Thus, having started entirely from the passive element in the good, the inquiry could only proceed later to the active element, and investigate the conduct of the man who is called good, no longer with reference to others, but to himself; specially setting itself the task of explaining both the purely objective respect which such conduct produces in others, and the peculiar contentment with himself which it clearly produces in the man himself, since he purchases it with sacrifices of another kind; and also, on the other hand, the inner pain which accompanies the bad disposition, whatever outward advantages it brings to him who entertains it. It was from this source that the ethical systems, both the philosophical and those which are supported by systems of religion, took their rise. Both seek constantly in some way or other to connect happiness with virtue, the former either by means of the principle of contradiction or that of sufficient reason, and thus to make happiness either identical with or

the consequence of virtue, always sophistically; the latter, by asserting the existence of other worlds than that which alone can be known to experience.[79] In our system, on the contrary, virtue will show itself, not as a striving after happiness, that is, well-being and life, but as an effort in quite an opposite direction.

It follows from what has been said above, that the *good* is, according to its concept, των πρως τι; thus every good is essentially relative, for its being consists in its relation to a desiring will. *Absolute good* is, therefore, a contradiction in terms; highest good, *summum bonum*, really signifies the same thing — a final satisfaction of the will, after which no new desire could arise, — a last motive, the attainment of which would afford enduring satisfaction of the will. But, according to the investigations which have already been conducted in this Fourth Book, such a consummation is not even thinkable. The will can just as little cease from willing altogether on account of some particular satisfaction, as time can end or begin; for it there is no such thing as a permanent fulfilment which shall completely and for ever satisfy its craving. It is the vessel of the Danaides; for it there is no highest good, no absolute good, but always a merely temporary good. If, however, we wish to give an honorary position, as it were emeritus, to an old expression, which from custom we do not like to discard altogether, we may, metaphorically and figuratively, call the complete self-effacement and denial of the will, the true absence of will, which alone for ever stills and silences its struggle, alone gives that contentment which can never again be disturbed, alone redeems the world, and which we shall now soon consider at the close of our whole investigation — the absolute good, the *summum bonum* — and regard it as the only radical cure of the disease of which all other means are only palliations or anodynes. In this sense the Greek τελος and also *finis bonorum* correspond to the thing still better. So much for the words *good* and *bad*; now for the thing itself.

If a man is always disposed to do *wrong* whenever the opportunity presents itself, and there is no external power to restrain him, we call him *bad*. According to our doctrine of wrong, this means that such a man does not merely assert the will to live as it appears in his own body, but in this assertion goes so far that he denies the will which appears in other individuals. This is shown by the fact that he desires their powers for the service of his own will, and seeks to destroy their existence when they stand in the way of its efforts. The ultimate source of this is a high degree of

egoism, the nature of which has been already explained. Two things are here apparent. In the first place, that in such a man an excessively vehement will to live expresses itself, extending far beyond the assertion of his own body; and, in the second place, that his knowledge, entirely given up to the principle of sufficient reason and involved in the *principium individuationis*, cannot get beyond the difference which this latter principle establishes between his own person and every one else. Therefore he seeks his own well-being alone, completely indifferent to that of all others, whose existence is to him altogether foreign and divided from his own by a wide gulf, and who are indeed regarded by him as mere masks with no reality behind them. And these two qualities are the constituent elements of the bad character.

This great intensity of will is in itself and directly a constant source of suffering. In the first place, because all volition as such arises from want; that is, suffering. (Therefore, as will be remembered, from the Third Book, the momentary cessation of all volition, which takes place whenever we give ourselves up to æsthetic contemplation, as pure will-less subject of knowledge, the correlative of the Idea, is one of the principal elements in our pleasure in the beautiful.) Secondly, because, through the causal connection of things, most of our desires must remain unfulfilled, and the will is oftener crossed than satisfied, and therefore much intense volition carries with it much intense suffering. For all suffering is simply unfulfilled and crossed volition; and even the pain of the body when it is injured or destroyed is as such only possible through the fact that the body is nothing but the will itself become object. Now on this account, because much intense suffering is inseparable from much intense volition, very bad men bear the stamp of inward suffering in the very expression of the countenance; even when they have attained every external happiness, they always look unhappy so long as they are not transported by some momentary ecstasy and are not dissembling. From this inward torment, which is absolutely and directly essential to them, there finally proceeds that delight in the suffering of others which does not spring from mere egoism, but is disinterested, and which constitutes *wickedness* proper, rising to the pitch of *cruelty*. For this the suffering of others is not a means for the attainment of the ends of its own will, but an end in itself. The more definite explanation of this phenomenon is as follows: — Since man is a manifestation of will illuminated by the clearest knowledge, he is always

contrasting the actual and felt satisfaction of his will with the merely possible satisfaction of it which knowledge presents to him. Hence arises envy: every privation is infinitely increased by the enjoyment of others, and relieved by the knowledge that others also suffer the same privation. Those ills which are common to all and inseparable from human life trouble us little, just as those which belong to the climate, to the whole country. The recollection of greater sufferings than our own stills our pain; the sight of the sufferings of others soothes our own. If, now, a man is filled with an exceptionally intense pressure of will, — if with burning eagerness he seeks to accumulate everything to slake the thirst of his egoism, and thus experiences, as he inevitably must, that all satisfaction is merely apparent, that the attained end never fulfils the promise of the desired object, the final appeasing of the fierce pressure of will, but that when fulfilled the wish only changes its form, and now torments him in a new one; and indeed that if at last all wishes are exhausted, the pressure of will itself remains without any conscious motive, and makes itself known to him with fearful pain as a feeling of terrible desolation and emptiness; if from all this, which in the case of the ordinary degrees of volition is only felt in a small measure, and only produces the ordinary degree of melancholy, in the case of him who is a manifestation of will reaching the point of extraordinary wickedness, there necessarily springs an excessive inward misery, an eternal unrest, an incurable pain; he seeks indirectly the alleviation which directly is denied him, — seeks to mitigate his own suffering by the sight of the suffering of others, which at the same time he recognises as an expression of his power. The suffering of others now becomes for him an end in itself, and is a spectacle in which he delights; and thus arises the phenomenon of pure cruelty, blood-thirstiness, which history exhibits so often in the Neros and Domitians, in the African Deis, in Robespierre, and the like.

The desire of revenge is closely related to wickedness. It recompenses evil with evil, not with reference to the future, which is the character of punishment, but merely on account of what has happened, what is past, as such, thus disinterestedly, not as a means, but as an end, in order to revel in the torment which the avenger himself has inflicted on the offender. What distinguishes revenge from pure wickedness, and to some extent excuses it, is an appearance of justice. For if the same act, which is now revenge, were to be done legally, that is, according to a previously determined and known

rule, and in a society which had sanctioned this rule, it would be punishment, and thus justice.

Besides the suffering which has been described, and which is inseparable from wickedness, because it springs from the same root, excessive vehemence of will, another specific pain quite different from this is connected with wickedness, which is felt in the case of every bad action, whether it be merely injustice proceeding from egoism or pure wickedness, and according to the length of its duration is called *the sting of conscience* or *remorse*. Now, whoever remembers and has present in his mind the content of the preceding portion of this Fourth Book, and especially the truth explained at the beginning of it, that life itself is always assured to the will to live, as its mere copy or mirror, and also the exposition of eternal justice, will find that the sting of conscience can have no other meaning than the following, *i.e.*, its content, abstractly expressed, is what follows, in which two parts are distinguished, which again, however, entirely coincide, and must be thought as completely united.

However closely the veil of Mâyâ may envelop the mind of the bad man, *i.e.*, however firmly he may be involved in the *principium individuationis*, according to which he regards his person as absolutely different and separated by a wide gulf from all others, a knowledge to which he clings with all his might, as it alone suits and supports his egoism, so that knowledge is almost always corrupted by will, yet there arises in the inmost depths of his consciousness the secret presentiment that such an order of things is only phenomenal, and that their real constitution is quite different. He has a dim foreboding that, however much time and space may separate him from other individuals and the innumerable miseries which they suffer, and even suffer through him, and may represent them as quite foreign to him, yet in themselves, and apart from the idea and its forms, it is the one will to live appearing in them all, which here failing to recognise itself, turns its weapons against itself, and, by seeking increased happiness in one of its phenomena, imposes the greatest suffering upon another. He dimly sees that he, the bad man, is himself this whole will; that consequently he is not only the inflicter of pain but also the endurer of it, from whose suffering he is only separated and exempted by an illusive dream, the form of which is space and time, which, however, vanishes away; that he must in reality pay for the pleasure with the pain, and that all suffering which he only knows as possible really concerns him as the will to live, inasmuch as the

possible and actual, the near and the distant in time and space, are only different for the knowledge of the individual, only by means of the *principium individuationis*, not in themselves. This is the truth which mythically, *i.e.*, adapted to the principle of sufficient reason, and so translated into the form of the phenomenal, is expressed in the transmigration of souls. Yet it has its purest expression, free from all foreign admixture, in that obscurely felt yet inconsolable misery called remorse. But this springs also from a second immediate knowledge, which is closely bound to the first — the knowledge of the strength with which the will to live asserts itself in the wicked individual, which extends far beyond his own individual phenomenon, to the absolute denial of the same will appearing in other individuals. Consequently the inward horror of the wicked man at his own deed, which he himself tries to conceal, contains, besides that presentment of the nothingness, the mere illusiveness of the *principium individuationis*, and of the distinction established by it between him and others; also the knowledge of the vehemence of his own will, the intensity with which he has seized upon life and attached himself closely to it, even that life whose terrible side he sees before him in the misery of those who are oppressed by him, and with which he is yet so firmly united, that just on this account the greatest atrocity proceeds from him himself, as a means for the fuller assertion of his own will. He recognises himself as the concentrated manifestation of the will to live, feels to what degree he is given up to life, and with it also to innumerable sufferings which are essential to it, for it has infinite time and infinite space to abolish the distinction between the possible and the actual, and to change all the sufferings which as yet are merely *known* to him into sufferings he has *experienced*. The millions of years of constant rebirth certainly exist, like the whole past and future, only in conception; occupied time, the form of the phenomenon of the will, is only the present, and for the individual time is ever new: it seems to him always as if he had newly come into being. For life is inseparable from the will to live, and the only form of life is the present. Death (the repetition of the comparison must be excused) is like the setting of the sun, which is only apparently swallowed up by the night, but in reality, itself the source of all light, burns without intermission, brings new days to new worlds, is always rising and always setting. Beginning and end only concern the individual through time, the form of the phenomenon for the idea. Outside time lies only the will, Kant's thing-in-itself, and its

adequate objectification, the Idea of Plato. Therefore suicide affords no escape; what every one in his inmost consciousness *wills*, that must he *be*; and what every one *is*, that he *wills*. Thus, besides the merely felt knowledge of the illusiveness and nothingness of the forms of the idea which separate individuals, it is the self-knowledge of one's own will and its degree that gives the sting to conscience. The course of life draws the image of the empirical character, whose original is the intelligible character, and horrifies the wicked man by this image. He is horrified all the same whether the image is depicted in large characters, so that the world shares his horror, or in such small ones that he alone sees it, for it only concerns him directly. The past would be a matter of indifference, and could not pain the conscience if the character did not feel itself free from all time and unalterable by it, so long as it does not deny itself. Therefore things which are long past still weigh on the conscience. The prayer, "Lead me not into temptation," means, "Let me not see what manner of person I am." In the might with which the bad man asserts life, and which exhibits itself to him in the sufferings which he inflicts on others, he measures how far he is from the surrender and denial of that will, the only possible deliverance from the world and its miseries. He sees how far he belongs to it, and how firmly he is bound to it; the *known* suffering of others has no power to move him; he is given up to life and *felt* suffering. It remains hidden whether this will ever break and overcome the vehemence of his will.

This exposition of the significance and inner nature of the *bad*, which as mere feeling, *i.e.*, not as distinct, abstract knowledge, is the content of *remorse*, will gain distinctness and completeness by the similar consideration of the *good* as a quality of human will, and finally of absolute resignation and holiness, which proceeds from it when it has attained its highest grade. For opposites always throw light upon each other, and the day at once reveals both itself and the night, as Spinoza admirably remarks.

§ 66. A theory of morals without proof, that is, mere moralising, can effect nothing, because it does not act as a motive. A theory of morals which does act as a motive can do so only by working on self-love. But what springs from this source has no moral worth. It follows from this that no genuine virtue can be produced through moral theory or abstract knowledge in general, but that such virtue must spring from that intuitive knowledge which recognises in the individuality of others the same nature as in our own.

For virtue certainly proceeds from knowledge, but not from the abstract knowledge that can be communicated through words. If it were so, virtue could be taught, and by here expressing in abstract language its nature and the knowledge which lies at its foundation, we should make every one who comprehends this even ethically better. But this is by no means the case. On the contrary, ethical discourses and preaching will just as little produce a virtuous man as all the systems of æsthetics from Aristotle downwards have succeeded in producing a poet. For the real inner nature of virtue the concept is unfruitful, just as it is in art, and it is only in a completely subordinate position that it can be of use as a tool in the elaboration and preserving of what has been ascertained and inferred by other means. *Velle non discitur.* Abstract dogmas are, in fact, without influence upon virtue, *i.e.*, upon the goodness of the disposition. False dogmas do not disturb it; true ones will scarcely assist it. It would, in fact, be a bad look-out if the cardinal fact in the life of man, his ethical worth, that worth which counts for eternity, were dependent upon anything the attainment of which is so much a matter of chance as is the case with dogmas, religious doctrines, and philosophical theories. For morality dogmas have this value only: The man who has become virtuous from knowledge of another kind, which is presently to be considered, possesses in them a scheme or formula according to which he accounts to his own reason, for the most part fictitiously, for his non-egoistical action, the nature of which it, *i.e.*, he himself, does not comprehend, and with which account he has accustomed it to be content.

Upon conduct, outward action, dogmas may certainly exercise a powerful influence, as also custom and example (the last because the ordinary man does not trust his judgment, of the weakness of which he is conscious, but only follows his own or some one else's experience), but the disposition is not altered in this way.[80] All abstract knowledge gives only motives; but, as was shown above, motives can only alter the direction of the will, not the will itself. All communicable knowledge, however, can only affect the will as a motive. Thus when dogmas lead it, what the man really and in general wills remains still the same. He has only received different thoughts as to the ways in which it is to be attained, and imaginary motives guide him just like real ones. Therefore, for example, it is all one, as regards his ethical worth, whether he gives large gifts to the poor, firmly persuaded that he will receive everything tenfold in a future life, or expends

the same sum on the improvement of an estate which will yield interest, certainly late, but all the more surely and largely. And he who for the sake of orthodoxy commits the heretic to the flames is as much a murderer as the bandit who does it for gain; and indeed, as regards inward circumstances, so also was he who slaughtered the Turks in the Holy Land, if, like the burner of heretics, he really did so because he thought that he would thereby gain a place in heaven. For these are careful only for themselves, for their own egoism, just like the bandit, from whom they are only distinguished by the absurdity of their means. From without, as has been said, the will can only be reached through motives, and these only alter the way in which it expresses itself, never the will itself. *Velle non discitur.*

In the case of good deeds, however, the doer of which appeals to dogmas, we must always distinguish whether these dogmas really are the motives which lead to the good deeds, or whether, as was said above, they are merely the illusive account of them with which he seeks to satisfy his own reason with regard to a good deed which really flows from quite a different source, a deed which he does because he is good, though he does not understand how to explain it rightly, and yet wishes to think something with regard to it. But this distinction is very hard to make, because it lies in the heart of a man. Therefore we can scarcely ever pass a correct moral judgment on the action of others, and very seldom on our own. The deeds and conduct of an individual and of a nation may be very much modified through dogmas, example, and custom. But in themselves all deeds (*opera operata*) are merely empty forms, and only the disposition which leads to them gives them moral significance. This disposition, however, may be quite the same when its outward manifestation is very different. With an equal degree of wickedness, one man may die on the wheel, and another in the bosom of his family. It may be the same grade of wickedness which expresses itself in one nation in the coarse characteristics of murder and cannibalism, and in another finely and softly in miniature, in court intrigues, oppressions, and delicate plots of every kind; the inner nature remains the same. It is conceivable that a perfect state, or perhaps indeed a complete and firmly believed doctrine of rewards and punishments after death, might prevent every crime; politically much would be gained thereby; morally, nothing; only the expression of the will in life would be restricted.

Thus genuine goodness of disposition, disinterested virtue, and pure nobility do not proceed from abstract knowledge. Yet they do proceed from

knowledge; but it is a direct intuitive knowledge, which can neither be reasoned away, nor arrived at by reasoning, a knowledge which, just because it is not abstract, cannot be communicated, but must arise in each for himself, which therefore finds its real and adequate expression not in words, but only in deeds, in conduct, in the course of the life of man. We who here seek the theory of virtue, and have therefore also to express abstractly the nature of the knowledge which lies at its foundation, will yet be unable to convey that knowledge itself in this expression. We can only give the concept of this knowledge, and thus always start from action in which alone it becomes visible, and refer to action as its only adequate expression. We can only explain and interpret action, *i.e.*, express abstractly what really takes place in it.

Before we speak of the *good* proper, in opposition to the *bad*, which has been explained, we must touch on an intermediate grade, the mere negation of the bad: this is *justice*. The nature of right and wrong has been fully explained above; therefore we may briefly say here, that he who voluntarily recognises and observes those merely moral limits between wrong and right, even where this is not secured by the state or any other external power, thus he who, according to our explanation, never carries the assertion of his own will so far as to deny the will appearing in another individual, is *just*. Thus, in order to increase his own well-being, he will not inflict suffering upon others, *i.e.*, he will commit no crime, he will respect the rights and the property of others. We see that for such a just man the *principium individuationis* is no longer, as in the case of the bad man, an absolute wall of partition. We see that he does not, like the bad man, merely assert his own manifestation of will and deny all others; that other persons are not for him mere masks, whose nature is quite different from his own; but he shows in his conduct that he also recognises his own nature — the will to live as a thing-in-itself, in the foreign manifestation which is only given to him as idea. Thus he finds himself again in that other manifestation, up to a certain point, that of doing no wrong, *i.e.*, abstaining from injury. To this extent, therefore, he sees through the *principium individuationis*, the veil of Mâyâ; so far he sets the being external to him on a level with his own — he does it no injury.

If we examine the inmost nature of this justice, there already lies in it the resolution not to go so far in the assertion of one's own will as to deny the manifestations of will of others, by compelling them to serve one's own.

One will therefore wish to render to others as much as one receives from them. The highest degree of this justice of disposition, which is, however, always united with goodness proper, whose character is no longer merely negative, extends so far that a man doubts his right to inherited property, wishes to support his body only by his own powers, mental and physical, feels every service of others and every luxury a reproach, and finally embraces voluntary poverty. Thus we see how Pascal, when he became an ascetic, would no longer permit any services to be rendered him, although he had servants enough; in spite of his constant bad health he made his bed himself, brought his own food from the kitchen, &c. ("Vie de Pascal, par sa Sœur," p. 19). Quite in keeping with this, it is reported that many Hindus, even Rajas with great wealth, expend it merely on the maintenance of their position, their court and attendants, and themselves observe with the greatest scrupulousness the maxim that a man should eat nothing that he has not himself both sowed and reaped. Yet a certain misunderstanding lies at the bottom of this; for one man, just because he is rich and powerful, can render such signal services to the whole of human society that they counterbalance the wealth he has inherited, for the secure possession of which he is indebted to society. In reality that excessive justice of such Hindus is already more than justice; it is actual renunciation, denial of the will to live, — asceticism, of which we shall speak last. On the other hand, pure idleness and living through the exertions of others, in the case of inherited wealth, without accomplishing anything, may be regarded as morally wrong, even if it must remain right according to positive laws.

We have found that voluntary justice has its inmost source in a certain degree of penetration of the *principium individuationis*, while the unjust remain entirely involved in this principle. This penetration may exist not only in the degree which is required for justice, but also in the higher degree which leads to benevolence and well-doing, to love of mankind. And this may take place however strong and energetic in itself the will which appears in such an individual may be. Knowledge can always counterbalance it in him, teach him to resist the tendency to wrong, and even produce in him every degree of goodness, and indeed of resignation. Thus the good man is by no means to be regarded as originally a weaker manifestation of will than the bad man, but it is knowledge which in him masters the blind striving of will. There are certainly individuals who merely seem to have a good disposition on account of the weakness of the

will appearing in them, but what they are soon appears from the fact that they are not capable of any remarkable self-conquest in order to perform a just or good deed.

If, however, as a rare exception, we meet a man who possesses a considerable income, but uses very little of it for himself and gives all the rest to the poor, while he denies himself many pleasures and comforts, and we seek to explain the action of this man, we shall find, apart altogether from the dogmas through which he tries to make his action intelligible to his reason, that the simplest general expression and the essential character of his conduct is that *he makes less distinction than is usually made between himself and others*. This distinction is so great in the eyes of many that the suffering of others is a direct pleasure to the wicked and a welcome means of happiness to the unjust. The merely just man is content not to cause it; and, in general, most men know and are acquainted with innumerable sufferings of others in their vicinity, but do not determine to mitigate them, because to do so would involve some self-denial on their part. Thus, in each of all these a strong distinction seems to prevail between his own ego and that of others; on the other hand, to the noble man we have imagined, this distinction is not so significant. The *principium individuationis*, the form of the phenomenon, no longer holds him so tightly in its grasp, but the suffering which he sees in others touches him almost as closely as his own. He therefore tries to strike a balance between them, denies himself pleasures, practises renunciation, in order to mitigate the sufferings of others. He sees that the distinction between himself and others, which to the bad man is so great a gulf, only belongs to a fleeting and illusive phenomenon. He recognises directly and without reasoning that the in-itself of his own manifestation is also that of others, the will to live, which constitutes the inner nature of everything and lives in all; indeed, that this applies also to the brutes and the whole of nature, and therefore he will not cause suffering even to a brute.[81]

He is now just as little likely to allow others to starve, while he himself has enough and to spare, as any one would be to suffer hunger one day in order to have more the next day than he could enjoy. For to him who does works of love the veil of Mâyâ has become transparent, the illusion of the *principium individuationis* has left him. He recognises himself, his will, in every being, and consequently also in the sufferer. He is now free from the perversity with which the will to live, not recognising itself, here in one

individual enjoys a fleeting and precarious pleasure, and there in another pays for it with suffering and starvation, and thus both inflicts and endures misery, not knowing that, like Thyestes, it eagerly devours its own flesh; and then, on the one hand, laments its undeserved suffering, and on the other hand transgresses without fear of Nemesis, always merely because, involved in the *principium individuationis*, thus generally in the kind of knowledge which is governed by the principle of sufficient reason, it does not recognise itself in the foreign phenomenon, and therefore does not perceive eternal justice. To be cured of this illusion and deception of Mâyâ, and to do works of love, are one and the same. But the latter is the necessary and inevitable symptom of that knowledge.

The opposite of the sting of conscience, the origin and significance of which is explained above, is the *good conscience*, the satisfaction which we experience after every disinterested deed. It arises from the fact that such a deed, as it proceeds from the direct recognition of our own inner being in the phenomenon of another, affords us also the verification of this knowledge, the knowledge that our true self exists not only in our own person, this particular manifestation, but in everything that lives. By this the heart feels itself enlarged, as by egoism it is contracted. For as the latter concentrates our interest upon the particular manifestation of our own individuality, upon which knowledge always presents to us the innumerable dangers which constantly threaten this manifestation, and anxiety and care becomes the key-note of our disposition; the knowledge that everything living is just as much our own inner nature, as is our own person, extends our interest to everything living; and in this way the heart is enlarged. Thus through the diminished interest in our own self, the anxious care for the self is attacked at its very root and limited; hence the peace, the unbroken serenity, which a virtuous disposition and a good conscience affords, and the more distinct appearance of this with every good deed, for it proves to ourselves the depth of that disposition. The egoist feels himself surrounded by strange and hostile individuals, and all his hope is centred in his own good. The good man lives in a world of friendly individuals, the well-being of any of whom he regards as his own. Therefore, although the knowledge of the lot of mankind generally does not make his disposition a joyful one, yet the permanent knowledge of his own nature in all living beings, gives him a certain evenness, and even serenity of disposition. For the interest which is extended to innumerable manifestations cannot cause such anxiety

as that which is concentrated upon one. The accidents which concern individuals collectively, equalise themselves, while those which happen to the particular individual constitute good or bad fortune.

Thus, though others have set up moral principles which they give out as prescriptions for virtue, and laws which it was necessary to follow, I, as has already been said, cannot do this because I have no "ought" or law to prescribe to the eternally free-will. Yet on the other hand, in the connection of my system, what to a certain extent corresponds and is analogous to that undertaking is the purely theoretical truth, of which my whole exposition may be regarded as merely an elaboration, that the will is the in-itself of every phenomenon but itself, as such, is free from the forms of the phenomenal, and consequently from multiplicity; a truth, which, with reference to action, I do not know how to express better than by the formula of the Vedas already quoted: "Tat twam asi!" (This thou art!) Whoever is able to say this to himself, with regard to every being with whom he comes in contact, with clear knowledge and firm inward conviction, is certain of all virtue and blessedness, and is on the direct road to salvation.

But before I go further, and, as the conclusion of my exposition, show how love, the origin and nature of which we recognised as the penetration of the *principium individuationis*, leads to salvation, to the entire surrender of the will to live, *i.e.*, of all volition, and also how another path, less soft but more frequented, leads men to the same goal, a paradoxical proposition must first be stated and explained; not because it is paradoxical, but because it is true, and is necessary to the completeness of the thought I have present. It is this: "All love (αγαπη, *caritas*) is sympathy."

§ 67. We have seen how justice proceeds from the penetration of the *principium individuationis* in a less degree, and how from its penetration in a higher degree there arises goodness of disposition proper, which shows itself as pure, *i.e.*, disinterested love towards others. When now the latter becomes perfect, it places other individuals and their fate completely on a level with itself and its own fate. Further than this it cannot go, for there exists no reason for preferring the individuality of another to its own. Yet the number of other individuals whose whole happiness or life is in danger may outweigh the regard for one's own particular well-being. In such a case, the character that has attained to the highest goodness and perfect nobility will entirely sacrifice its own well-being, and even its life, for the well-being of many others. So died Codrus, and Leonidas, and Regulus, and

Decius Mus, and Arnold von Winkelried; so dies every one who voluntarily and consciously faces certain death for his friends or his country. And they also stand on the same level who voluntarily submit to suffering and death for maintaining what conduces and rightly belongs to the welfare of all mankind; that is, for maintaining universal and important truths and destroying great errors. So died Socrates and Giordano Bruno, and so many a hero of the truth suffered death at the stake at the hands of the priests.

Now, however, I must remind the reader, with reference to the paradox stated above, that we found before that suffering is essential to life as a whole, and inseparable from it. And that we saw that every wish proceeds from a need, from a want, from suffering, and that therefore every satisfaction is only the removal of a pain, and brings no positive happiness; that the joys certainly lie to the wish, presenting themselves as a positive good, but in truth they have only a negative nature, and are only the end of an evil. Therefore what goodness, love, and nobleness do for others, is always merely an alleviation of their suffering, and consequently all that can influence them to good deeds and works of love, is simply the *knowledge of the suffering of others*, which is directly understood from their own suffering and placed on a level with it. But it follows from this that pure love (αγαπη, *caritas*) is in its nature sympathy; whether the suffering it mitigates, to which every unsatisfied wish belongs, be great or small. Therefore we shall have no hesitation, in direct contradiction to Kant, who will only recognise all true goodness and all virtue to be such, if it has proceeded from abstract reflection, and indeed from the conception of duty and of the categorical imperative, and explains felt sympathy as weakness, and by no means virtue, we shall have no hesitation, I say, in direct contradiction to Kant, in saying: the mere concept is for genuine virtue just as unfruitful as it is for genuine art: all true and pure love is sympathy, and all love which is not sympathy is selfishness. Ερος is selfishness, αγαπη is sympathy. Combinations of the two frequently occur. Indeed genuine friendship is always a mixture of selfishness and sympathy; the former lies in the pleasure experienced in the presence of the friend, whose individuality corresponds to our own, and this almost always constitutes the greatest part; sympathy shows itself in the sincere participation in his joy and grief, and the disinterested sacrifices made in respect of the latter. Thus Spinoza says: *Benevolentia nihil aliud est, quam cupiditas ex commiseratione orta* (Eth. iii. pr. 27, cor. 3, schol.) As a confirmation of our

paradoxical proposition it may be observed that the tone and words of the language and caresses of pure love, entirely coincide with the tones of sympathy; and we may also remark in passing that in Italian sympathy and true love are denoted by the same word *pietà*.

This is also the place to explain one of the most striking peculiarities of human nature, *weeping*, which, like laughter, belongs to those qualities which distinguish man from the brutes. Weeping is by no means a direct expression of pain, for it occurs where there is very little pain. In my opinion, indeed, we never weep directly on account of the pain we experience, but always merely on account of its repetition in reflection. We pass from the felt pain, even when it is physical, to a mere idea of it, and then find our own state so deserving of sympathy that we are firmly and sincerely convinced that if another were the sufferer, we would be full of sympathy, and love to relieve him. But now we ourselves are the object of our own sympathy; with the most benevolent disposition we are ourselves most in need of help; we feel that we suffer more than we could see another suffer; and in this very complex frame of mind, in which the directly felt suffering only comes to perception by a doubly circuitous route, imagined as the suffering of another, sympathised with as such, and then suddenly perceived again as directly our own, — in this complex frame of mind, I say, Nature relieves itself through that remarkable physical conflict. *Weeping* is accordingly *sympathy with our own selves*, or sympathy directed back on its source. It is therefore conditional upon the capacity for love and sympathy, and also upon imagination. Therefore men who are either hard-hearted or unimaginative do not weep easily, and weeping is even always regarded as a sign of a certain degree of goodness of character, and disarms anger, because it is felt that whoever can still weep, must necessarily always be capable of love, *i.e.*, sympathy towards others, for this enters in the manner described into the disposition that leads to weeping. The description which Petrarch gives of the rising of his own tears, naïvely and truly expressing his feeling, entirely agrees with the explanation we have given —

> "I vo pensando: e nel pensar m' assale
> *Una pietà si forte di me stesso*,
> Che mi conduce spesso,
> Ad alto lagrimar, ch'i non soleva."[82]

What has been said is also confirmed by the fact that children who have been hurt generally do not cry till some one commiserates them; thus not on account of the pain, but on account of the idea of it. When we are moved to tears, not through our own suffering but through that of another, this happens as follows. Either we vividly put ourselves in the place of the sufferer by imagination, or see in his fate the lot of humanity as a whole, and consequently, first of all, our own lot; and thus, in a very roundabout way, it is yet always about ourselves that we weep, sympathy with ourselves which we feel. This seems to be the principal reason of the universal, and thus natural, weeping in the case of death. The mourner does not weep for his loss; he would be ashamed of such egotistical tears, instead of which he is sometimes ashamed of not weeping. First of all he certainly weeps for the fate of the dead, but he also weeps when, after long, heavy, and incurable suffering, death was to this man a wished-for deliverance. Thus, principally, he is seized with sympathy for the lot of all mankind, which is necessarily finite, so that every life, however aspiring, and often rich in deeds, must be extinguished and become nothing. But in this lot of mankind the mourner sees first of all his own, and this all the more, the more closely he is related to him who has died, thus most of all if it is his father. Although to his father his life was misery through age and sickness, and though his helplessness was a heavy burden to his son, yet that son weeps bitterly over the death of his father for the reason which has been given.[83]

§ 68. After this digression about the identity of pure love and sympathy, the final return of which upon our own individuality has, as its symptom, the phenomenon of weeping, I now take up the thread of our discussion of the ethical significance of action, in order to show how, from the same source from which all goodness, love, virtue, and nobility of character spring, there finally arises that which I call the denial of the will to live.

We saw before that hatred and wickedness are conditioned by egoism, and egoism rests on the entanglement of knowledge in the *principium individuationis*. Thus we found that the penetration of that *principium individuationis* is the source and the nature of justice, and when it is carried further, even to its fullest extent, it is the source and nature of love and nobility of character. For this penetration alone, by abolishing the distinction between our own individuality and that of others, renders possible and explains perfect goodness of disposition, extending to disinterested love and the most generous self-sacrifice for others.

If, however, this penetration of the *principium individuationis*, this direct knowledge of the identity of will in all its manifestations, is present in a high degree of distinctness, it will at once show an influence upon the will which extends still further. If that veil of Mâyâ, the *principium individuationis*, is lifted from the eyes of a man to such an extent that he no longer makes the egotistical distinction between his person and that of others, but takes as much interest in the sufferings of other individuals as in his own, and therefore is not only benevolent in the highest degree, but even ready to sacrifice his own individuality whenever such a sacrifice will save a number of other persons, then it clearly follows that such a man, who recognises in all beings his own inmost and true self, must also regard the infinite suffering of all suffering beings as his own, and take on himself the pain of the whole world. No suffering is any longer strange to him. All the miseries of others which he sees and is so seldom able to alleviate, all the miseries he knows directly, and even those which he only knows as possible, work upon his mind like his own. It is no longer the changing joy and sorrow of his own person that he has in view, as is the case with him who is still involved in egoism; but, since he sees through the *principium individuationis*, all lies equally near him. He knows the whole, comprehends its nature, and finds that it consists in a constant passing away, vain striving, inward conflict, and continual suffering. He sees wherever he looks suffering humanity, the suffering brute creation, and a world that passes away. But all this now lies as near him as his own person lies to the egoist. Why should he now, with such knowledge of the world, assert this very life through constant acts of will, and thereby bind himself ever more closely to it, press it ever more firmly to himself? Thus he who is still involved in the *principium individuationis*, in egoism, only knows particular things and their relation to his own person, and these constantly become new *motives* of his volition. But, on the other hand, that knowledge of the whole, of the nature of the thing-in-itself which has been described, becomes a *quieter* of all and every volition. The will now turns away from life; it now shudders at the pleasures in which it recognises the assertion of life. Man now attains to the state of voluntary renunciation, resignation, true indifference, and perfect will-lessness. If at times, in the hard experience of our own suffering, or in the vivid recognition of that of others, the knowledge of the vanity and bitterness of life draws nigh to us also who are still wrapt in the veil of Mâyâ, and we would like to destroy the sting of the

desires, close the entrance against all suffering, and purify and sanctify ourselves by complete and final renunciation; yet the illusion of the phenomenon soon entangles us again, and its motives influence the will anew; we cannot tear ourselves free. The allurement of hope, the flattery of the present, the sweetness of pleasure, the well-being which falls to our lot, amid the lamentations of a suffering world governed by chance and error, draws us back to it and rivets our bonds anew. Therefore Jesus says: "It is easier for a camel to go through the eye of a needle, than for a rich man to enter into the kingdom of God."

If we compare life to a course or path through which we must unceasingly run — a path of red-hot coals, with a few cool places here and there; then he who is entangled in delusion is consoled by the cool places, on which he now stands, or which he sees near him, and sets out to run through the course. But he who sees through the *principium individuationis*, and recognises the real nature of the thing-in-itself, and thus the whole, is no longer susceptible of such consolation; he sees himself in all places at once, and withdraws. His will turns round, no longer asserts its own nature, which is reflected in the phenomenon, but denies it. The phenomenon by which this change is marked, is the transition from virtue to asceticism. That is to say, it no longer suffices for such a man to love others as himself, and to do as much for them as for himself; but there arises within him a horror of the nature of which his own phenomenal existence is an expression, the will to live, the kernel and inner nature of that world which is recognised as full of misery. He therefore disowns this nature which appears in him, and is already expressed through his body, and his action gives the lie to his phenomenal existence, and appears in open contradiction to it. Essentially nothing else but a manifestation of will, he ceases to will anything, guards against attaching his will to anything, and seeks to confirm in himself the greatest indifference to everything. His body, healthy and strong, expresses through the genitals, the sexual impulse; but he denies the will and gives the lie to the body; he desires no sensual gratification under any condition. Voluntary and complete chastity is the first step in asceticism or the denial of the will to live. It thereby denies the assertion of the will which extends beyond the individual life, and gives the assurance that with the life of this body, the will, whose manifestation it is, ceases. Nature, always true and naïve, declares that if this maxim became universal, the human race would die out; and I think I may assume, in accordance with

what was said in the Second Book about the connection of all manifestations of will, that with its highest manifestation, the weaker reflection of it would also pass away, as the twilight vanishes along with the full light. With the entire abolition of knowledge, the rest of the world would of itself vanish into nothing; for without a subject there is no object. I should like here to refer to a passage in the Vedas, where it is said: "As in this world hungry infants press round their mother; so do all beings await the holy oblation." (Asiatic Researches, vol. viii.; Colebrooke, On the Vedas, Abstract of the Sama-Veda; also in Colebrooke's Miscellaneous Essays, vol. i. p. 79.) Sacrifice means resignation generally, and the rest of nature must look for its salvation to man who is at once the priest and the sacrifice. Indeed it deserves to be noticed as very remarkable, that this thought has also been expressed by the admirable and unfathomably profound Angelus Silesius, in the little poem entitled, "Man brings all to God;" it runs, "Man! all loves thee; around thee great is the throng. All things flee to thee that they may attain to God." But a yet greater mystic, Meister Eckhard, whose wonderful writings are at last accessible (1857) through the edition of Franz Pfeiffer, says the same thing (p. 459) quite in the sense explained here: "I bear witness to the saying of Christ. I, if I be lifted up from the earth, will draw all things unto me (John xii. 32). So shall the good man draw all things up to God, to the source whence they first came. The Masters certify to us that all creatures are made for the sake of man. This is proved in all created things, by the fact that the one makes the use of the other; the ox makes use of the grass, the fish of the water, the bird of the air, the wild beast of the forest. Thus, all created things become of use to the good man. A good man brings to God the one created thing in the other." He means to say, that man makes use of the brutes in this life because, in and with himself, he saves them also. It also seems to me that that difficult passage in the Bible, Rom. viii. 21-24, must be interpreted in this sense.

In Buddhism also, there is no lack of expressions of this truth. For example, when Buddha, still as Bodisatwa, has his horse saddled for the last time, for his flight into the wilderness from his father's house, he says these lines to the horse: "Long hast thou existed in life and in death, but now thou shalt cease from carrying and drawing. Bear me but this once more, O Kantakana, away from here, and when I have attained to the Law (have

become Buddha) I will not forget thee" (Foe Koue Ki, trad. p. Abel Rémusat, p. 233).

Asceticism then shows itself further in voluntary and intentional poverty, which not only arises *per accidens*, because the possessions are given away to mitigate the sufferings of others, but is here an end in itself, is meant to serve as a constant mortification of will, so that the satisfaction of the wishes, the sweet of life, shall not again arouse the will, against which self-knowledge has conceived a horror. He who has attained to this point, still always feels, as a living body, as concrete manifestation of will, the natural disposition for every kind of volition; but he intentionally suppresses it, for he compels himself to refrain from doing all that he would like to do, and to do all that he would like not to do, even if this has no further end than that of serving as a mortification of will. Since he himself denies the will which appears in his own person, he will not resist if another does the same, *i.e.*, inflicts wrongs upon him. Therefore every suffering coming to him from without, through chance or the wickedness of others, is welcome to him, every injury, ignominy, and insult; he receives them gladly as the opportunity of learning with certainty that he no longer asserts the will, but gladly sides with every enemy of the manifestation of will which is his own person. Therefore he bears such ignominy and suffering with inexhaustible patience and meekness, returns good for evil without ostentation, and allows the fire of anger to rise within him just as little as that of the desires. And he mortifies not only the will itself, but also its visible form, its objectivity, the body. He nourishes it sparingly, lest its excessive vigour and prosperity should animate and excite more strongly the will, of which it is merely the expression and the mirror. So he practises fasting, and even resorts to chastisement and self-inflicted torture, in order that, by constant privation and suffering, he may more and more break down and destroy the will, which he recognises and abhors as the source of his own suffering existence and that of the world. If at last death comes, which puts an end to this manifestation of that will, whose existence here has long since perished through free-denial of itself, with the exception of the weak residue of it which appears as the life of this body; it is most welcome, and is gladly received as a longed-for deliverance. Here it is not, as in the case of others, merely the manifestation which ends with death; but the inner nature itself is abolished, which here existed only in the manifestation, and that in a very

weak degree;[84] this last slight bond is now broken. For him who thus ends, the world has ended also.

And what I have here described with feeble tongue and only in general terms, is no philosophical fable, invented by myself, and only of to-day; no, it was the enviable life of so many saints and beautiful souls among Christians, and still more among Hindus and Buddhists, and also among the believers of other religions. However different were the dogmas impressed on their reason, the same inward, direct, intuitive knowledge, from which alone all virtue and holiness proceed, expressed itself in precisely the same way in the conduct of life. For here also the great distinction between intuitive and abstract knowledge shows itself; a distinction which is of such importance and universal application in our whole investigation, and which has hitherto been too little attended to. There is a wide gulf between the two, which can only be crossed by the aid of philosophy, as regards the knowledge of the nature of the world. Intuitively or *in concreto*, every man is really conscious of all philosophical truths, but to bring them to abstract knowledge, to reflection, is the work of philosophy, which neither ought nor is able to do more than this.

Thus it may be that the inner nature of holiness, self-renunciation, mortification of our own will, asceticism, is here for the first time expressed abstractly, and free from all mythical elements, as *denial of the will to live*, appearing after the complete knowledge of its own nature has become a quieter of all volition. On the other hand, it has been known directly and realised in practice by saints and ascetics, who had all the same inward knowledge, though they used very different language with regard to it, according to the dogmas which their reason had accepted, and in consequence of which an Indian, a Christian, or a Lama saint must each give a very different account of his conduct, which is, however, of no importance as regards the fact. A saint may be full of the absurdest superstition, or, on the contrary, he may be a philosopher, it is all the same. His conduct alone certifies that he is a saint, for, in a moral regard, it proceeds from knowledge of the world and its nature, which is not abstractly but intuitively and directly apprehended, and is only expressed by him in any dogma for the satisfaction of his reason. It is therefore just as little needful that a saint should be a philosopher as that a philosopher should be a saint; just as it is not necessary that a perfectly beautiful man should be a great sculptor, or that a great sculptor should himself be a

beautiful man. In general, it is a strange demand upon a moralist that he should teach no other virtue than that which he himself possesses. To repeat the whole nature of the world abstractly, universally, and distinctly in concepts, and thus to store up, as it were, a reflected image of it in permanent concepts always at the command of the reason; this and nothing else is philosophy. I refer the reader to the passage quoted from Bacon in the First Book.

But the description I have given above of the denial of the will to live, of the conduct of a beautiful soul, of a resigned and voluntarily expiating saint, is merely abstract and general, and therefore cold. As the knowledge from which the denial of the will proceeds is intuitive and not abstract, it finds its most perfect expression, not in abstract conceptions, but in deeds and conduct. Therefore, in order to understand fully what we philosophically express as denial of the will to live, one must come to know examples of it in experience and actual life. Certainly they are not to be met with in daily experience: *Nam omnia præclara tam difficilia quam rara sunt*, Spinoza admirably says. Therefore, unless by a specially happy fate we are made eye-witnesses, we have to content ourselves with descriptions of the lives of such men. Indian literature, as we see from the little that we as yet know through translations, is very rich in descriptions of the lives of saints, penitents, Samanas or ascetics, Sannyâsis or mendicants, and whatever else they may be called. Even the well-known "Mythologie des Indous, par Mad. de Polier," though by no means to be commended in every respect, contains many excellent examples of this kind (especially in ch. 13, vol. ii.) Among Christians also there is no lack of examples which afford us the illustrations we desire. See the biographies, for the most part badly written, of those persons who are sometimes called saintly souls, sometimes pietists, quietists, devout enthusiasts, and so forth. Collections of such biographies have been made at various times, such as Tersteegen's "Leben heiliger Seelen," Reiz's "Geschichte der Wiedergeborennen," in our own day, a collection by Kanne, which, with much that is bad, yet contains some good, and especially the "Leben der Beata Sturmin." To this category very properly belongs the life of St. Francis of Assisi, that true personification of the ascetic, and prototype of all mendicant friars. His life, described by his younger contemporary, St. Bonaventura, also famous as a scholastic, has recently been republished. "Vita S. Francisci a S. Bonaventura concinnata" (Soest, 1847), though shortly before a painstaking and detailed biography,

making use of all sources of information, appeared in France, “Histoire de S. François d’Assise, par Chavin de Mallan” (1845). As an Oriental parallel of these monastic writings we have the very valuable work of Spence Hardy, “Eastern Monachism; an Account of the Order of Mendicants founded by Gotama Budha” (1850). It shows us the same thing in another dress. We also see what a matter of indifference it is whether it proceeds from a theistical or an atheistical religion. But as a special and exceedingly full example and practical illustration of the conceptions I have established, I can thoroughly recommend the “Autobiography of Madame de Guion.” To become acquainted with this great and beautiful soul, the very thought of whom always fills me with reverence, and to do justice to the excellence of her disposition while making allowance for the superstition of her reason, must be just as delightful to every man of the better sort as with vulgar thinkers, *i.e.*, the majority, that book will always stand in bad repute. For it is the case with regard to everything, that each man can only prize that which to a certain extent is analogous to him and for which he has at least a slight inclination. This holds good of ethical concerns as well as of intellectual. We might to a certain extent regard the well-known French biography of Spinoza as a case in point, if we used as a key to it that noble introduction to his very insufficient essay, “De Emendatione Intellectus,” a passage which I can also recommend as the most effectual means I know of stilling the storm of the passions. Finally, even the great Goethe, Greek as he is, did not think it below his dignity to show us this most beautiful side of humanity in the magic mirror of poetic art, for he represented the life of Fräulein Klettenberg in an idealised form in his “Confessions of a Beautiful Soul,” and later, in his own biography, gave us also an historical account of it. Besides this, he twice told the story of the life of St. Philippo Neri. The history of the world, will, and indeed must, keep silence about the men whose conduct is the best and only adequate illustration of this important point of our investigation, for the material of the history of the world is quite different, and indeed opposed to this. It is not the denial of the will to live, but its assertion and its manifestation in innumerable individuals in which its conflict with itself at the highest grade of its objectification appears with perfect distinctness, and brings before our eyes, now the ascendancy of the individual through prudence, now the might of the many through their mass, now the might of chance personified as fate, always the vanity and emptiness of the whole effort. We, however, do not follow here

the course of phenomena in time, but, as philosophers, we seek to investigate the ethical significance of action, and take this as the only criterion of what for us is significant and important. Thus we will not be withheld by any fear of the constant numerical superiority of vulgarity and dulness from acknowledging that the greatest, most important, and most significant phenomenon that the world can show is not the conqueror of the world, but the subduer of it; is nothing but the quiet, unobserved life of a man who has attained to the knowledge in consequence of which he surrenders and denies that will to live which fills everything and strives and strains in all, and which first gains freedom here in him alone, so that his conduct becomes the exact opposite of that of other men. In this respect, therefore, for the philosopher, these accounts of the lives of holy, self-denying men, badly as they are generally written, and mixed as they are with superstition and nonsense, are, because of the significance of the material, immeasurably more instructive and important than even Plutarch and Livy.

It will further assist us much in obtaining a more definite and full knowledge of what we have expressed abstractly and generally, according to our method of exposition, as the denial of the will to live, if we consider the moral teaching that has been imparted with this intention, and by men who were full of this spirit; and this will also show how old our view is, though the pure philosophical expression of it may be quite new. The teaching of this kind which lies nearest to hand is Christianity, the ethics of which are entirely in the spirit indicated, and lead not only to the highest degrees of human love, but also to renunciation. The germ of this last side of it is certainly distinctly present in the writings of the Apostles, but it was only fully developed and expressed later. We find the Apostles enjoining the love of our neighbour as ourselves, benevolence, the requital of hatred with love and well-doing, patience, meekness, the endurance of all possible injuries without resistance, abstemiousness in nourishment to keep down lust, resistance to sensual desire, if possible, altogether. We already see here the first degrees of asceticism, or denial of the will proper. This last expression denotes that which in the Gospels is called denying ourselves and taking up the cross (Matt. xvi. 24, 25; Mark viii. 34, 35; Luke ix. 23, 24, xiv. 26, 27, 33). This tendency soon developed itself more and more, and was the origin of hermits, anchorites, and monasticism — an origin which in itself was pure and holy, but for that very reason unsuitable for the

great majority of men; therefore what developed out of it could only be hypocrisy and wickedness, for *abusus optimi pessimus*. In more developed Christianity, we see that seed of asceticism unfold into the full flower in the writings of the Christian saints and mystics. These preach, besides the purest love, complete resignation, voluntary and absolute poverty, genuine calmness, perfect indifference to all worldly things, dying to our own will and being born again in God, entire forgetting of our own person, and sinking ourselves in the contemplation of God. A full exposition of this will be found in Fénélon's "Explication des Maximes des Saints sur la Vie Interieure." But the spirit of this development of Christianity is certainly nowhere so fully and powerfully expressed as in the writings of the German mystics, in the works of Meister Eckhard, and in that justly famous book "Die Deutsche Theologie," of which Luther says in the introduction to it which he wrote, that with the exception of the Bible and St. Augustine, he had learnt more from it of what God, Christ, and man are than from any other book. Yet we only got the genuine and correct text of it in the year 1851, in the Stuttgart edition by Pfeiffer. The precepts and doctrines which are laid down there are the most perfect exposition, sprung from deep inward conviction of what I have presented as the denial of the will. It should therefore be studied more closely in that form before it is dogmatised about with Jewish-Protestant assurance. Tauler's "Nachfolgung des armen Leben Christi," and also his "Medulla Animæ," are written in the same admirable spirit, though not quite equal in value to that work. In my opinion the teaching of these genuine Christian mystics, when compared with the teaching of the New Testament, is as alcohol to wine, or what becomes visible in the New Testament as through a veil and mist appears to us in the works of the mystics without cloak or disguise, in full clearness and distinctness. Finally, the New Testament might be regarded as the first initiation, the mystics as the second, — σμικρα και μεγαλα μυστηρια.

We find, however, that which we have called the denial of the will to live more fully developed, more variously expressed, and more vividly represented in the ancient Sanscrit writings than could be the case in the Christian Church and the Western world. That this important ethical view of life could here attain to a fuller development and a more distinct expression is perhaps principally to be ascribed to the fact that it was not confined by an element quite foreign to it, as Christianity is by the Jewish theology, to which its sublime author had necessarily to adopt and accommodate it,

partly consciously, partly, it may be, unconsciously. Thus Christianity is made up of two very different constituent parts, and I should like to call the purely ethical part especially and indeed exclusively Christian, and distinguish it from the Jewish dogmatism with which it is combined. If, as has often been feared, and especially at the present time, that excellent and salutary religion should altogether decline, I should look for the reason of this simply in the fact that it does not consist of one single element, but of two originally different elements, which have only been combined through the accident of history. In such a case dissolution had to follow through the separation of these elements, arising from their different relationship to and reaction against the progressive spirit of the age. But even after this dissolution the purely ethical part must always remain uninjured, because it is indestructible. Our knowledge of Hindu literature is still very imperfect. Yet, as we find their ethical teaching variously and powerfully expressed in the Vedas, Puranas, poems, myths, legends of their saints, maxims and precepts,[85] we see that it inculcates love of our neighbour with complete renunciation of self-love; love generally, not confined to mankind, but including all living creatures; benevolence, even to the giving away of the hard-won wages of daily toil; unlimited patience towards all who injure us; the requital of all wickedness, however base, with goodness and love; voluntary and glad endurance of all ignominy; abstinence from all animal food; perfect chastity and renunciation of all sensual pleasure for him who strives after true holiness; the surrender of all possessions, the forsaking of every dwelling-place and of all relatives; deep unbroken solitude, spent in silent contemplation, with voluntary penance and terrible slow self-torture for the absolute mortification of the will, torture which extends to voluntary death by starvation, or by men giving themselves up to crocodiles, or flinging themselves over the sacred precipice in the Himalayas, or being buried alive, or, finally, by flinging themselves under the wheels of the huge car of an idol drawn along amid the singing, shouting, and dancing of bayaderes. And even yet these precepts, whose origin reaches back more than four thousand years, are carried out in practice, in some cases even to the utmost extreme,[86] and this notwithstanding the fact that the Hindu nation has been broken up into so many parts. A religion which demands the greatest sacrifices, and which has yet remained so long in practice in a nation that embraces so many millions of persons, cannot be an arbitrarily invented superstition, but must have its foundation in the nature of man. But

besides this, if we read the life of a Christian penitent or saint, and also that of a Hindu saint, we cannot sufficiently wonder at the harmony we find between them. In the case of such radically different dogmas, customs, and circumstances, the inward life and effort of both is the same. And the same harmony prevails in the maxims prescribed for both of them. For example, Tauler speaks of the absolute poverty which one ought to seek, and which consists in giving away and divesting oneself completely of everything from which one might draw comfort or worldly pleasure, clearly because all this constantly affords new nourishment to the will, which it is intended to destroy entirely. And as an Indian counterpart of this, we find in the precepts of Fo that the Saniassi, who ought to be without a dwelling and entirely without property, is further finally enjoined not to lay himself down often under the same tree, lest he should acquire a preference or inclination for it above other trees. The Christian mystic and the teacher of the Vedanta philosophy agree in this respect also, they both regard all outward works and religious exercises as superfluous for him who has attained to perfection. So much agreement in the case of such different ages and nations is a practical proof that what is expressed here is not, as optimistic dulness likes to assert, an eccentricity and perversity of the mind, but an essential side of human nature, which only appears so rarely because of its excellence.

I have now indicated the sources from which there may be obtained a direct knowledge, drawn from life itself, of the phenomena in which the denial of the will to live exhibits itself. In some respects this is the most important point of our whole work; yet I have only explained it quite generally, for it is better to refer to those who speak from direct experience, than to increase the size of this book unduly by weak repetitions of what is said by them.

I only wish to add a little to the general indication of the nature of this state. We saw above that the wicked man, by the vehemence of his volition, suffers constant, consuming, inward pain, and finally, if all objects of volition are exhausted, quenches the fiery thirst of his self-will by the sight of the suffering of others. He, on the contrary, who has attained to the denial of the will to live, however poor, joyless, and full of privation his condition may appear when looked at externally, is yet filled with inward joy and the true peace of heaven. It is not the restless strain of life, the jubilant delight which has keen suffering as its preceding or succeeding condition, in the

experience of the man who loves life; but it is a peace that cannot be shaken, a deep rest and inward serenity, a state which we cannot behold without the greatest longing when it is brought before our eyes or our imagination, because we at once recognise it as that which alone is right, infinitely surpassing everything else, upon which our better self cries within us the great *sapere aude*. Then we feel that every gratification of our wishes won from the world is merely like the alms which the beggar receives from life to-day that he may hunger again on the morrow; resignation, on the contrary, is like an inherited estate, it frees the owner for ever from all care.

It will be remembered from the Third Book that the æsthetic pleasure in the beautiful consists in great measure in the fact that in entering the state of pure contemplation we are lifted for the moment above all willing, *i.e.*, all wishes and cares; we become, as it were, freed from ourselves. We are no longer the individual whose knowledge is subordinated to the service of its constant willing, the correlative of the particular thing to which objects are motives, but the eternal subject of knowing purified from will, the correlative of the Platonic Idea. And we know that these moments in which, delivered from the ardent strain of will, we seem to rise out of the heavy atmosphere of earth, are the happiest which we experience. From this we can understand how blessed the life of a man must be whose will is silenced, not merely for a moment, as in the enjoyment of the beautiful, but for ever, indeed altogether extinguished, except as regards the last glimmering spark that retains the body in life, and will be extinguished with its death. Such a man, who, after many bitter struggles with his own nature, has finally conquered entirely, continues to exist only as a pure, knowing being, the undimmed mirror of the world. Nothing can trouble him more, nothing can move him, for he has cut all the thousand cords of will which hold us bound to the world, and, as desire, fear, envy, anger, drag us hither and thither in constant pain. He now looks back smiling and at rest on the delusions of this world, which once were able to move and agonise his spirit also, but which now stand before him as utterly indifferent to him, as the chess-men when the game is ended, or as, in the morning, the cast-off masquerading dress which worried and disquieted us in a night in Carnival. Life and its forms now pass before him as a fleeting illusion, as a light morning dream before half-waking eyes, the real world already shining through it so that it can no longer deceive; and like this morning dream, they finally vanish altogether without any violent transition. From this we

can understand the meaning of Madame Guion when towards the end of her autobiography she often expresses herself thus: “Everything is alike to me; I *cannot* will anything more: often I know not whether I exist or not.” In order to express how, after the extinction of the will, the death of the body (which is indeed only the manifestation of the will, and therefore loses all significance when the will is abolished) can no longer have any bitterness, but is very welcome, I may be allowed to quote the words of that holy penitent, although they are not very elegantly turned: “*Midi de la gloire; jour où il n’y a plus de nuit; vie qui ne craint plus la mort, dans la mort même: parceque la mort a vaincu la mort, et que celui qui a souffert la première mort, ne goutera plus la seconde mort*” (Vie de Mad. de Guion, vol. ii. p. 13).

We must not, however, suppose that when, by means of the knowledge which acts as a quieter of will, the denial of the will to live has once appeared, it never wavers or vacillates, and that we can rest upon it as on an assured possession. Rather, it must ever anew be attained by a constant battle. For since the body is the will itself only in the form of objectivity or as manifestation in the world as idea, so long as the body lives, the whole will to live exists potentially, and constantly strives to become actual, and to burn again with all its ardour. Therefore that peace and blessedness in the life of holy men which we have described is only found as the flower which proceeds from the constant victory over the will, and the ground in which it grows is the constant battle with the will to live, for no one can have lasting peace upon earth. We therefore see the histories of the inner life of saints full of spiritual conflicts, temptations, and absence of grace, *i.e.*, the kind of knowledge which makes all motives ineffectual, and as an universal quieter silences all volition, gives the deepest peace and opens the door of freedom. Therefore also we see those who have once attained to the denial of the will to live strive with all their might to keep upon this path, by enforced renunciation of every kind, by penance and severity of life, and by selecting whatever is disagreeable to them, all in order to suppress the will, which is constantly springing up anew. Hence, finally, because they already know the value of salvation, their anxious carefulness to retain the hard-won blessing, their scruples of conscience about every innocent pleasure, or about every little excitement of their vanity, which here also dies last, the most immovable, the most active, and the most foolish of all the inclinations of man. By the term *asceticism*, which I have used so often, I mean in its

narrower sense this *intentional* breaking of the will by the refusal of what is agreeable and the selection of what is disagreeable, the voluntarily chosen life of penance and self-chastisement for the continual mortification of the will.

We see this practised by him who has attained to the denial of the will in order to enable him to persist in it; but suffering in general, as it is inflicted by fate, is a second way (δευτερος πλους[87]) of attaining to that denial. Indeed, we may assume that most men only attain to it in this way, and that it is the suffering which is personally experienced, not that which is merely known, which most frequently produces complete resignation, often only at the approach of death. For only in the case of a few is the mere knowledge which, seeing through the *principium individuationis*, first produces perfect goodness of disposition and universal love of humanity, and finally enables them to regard all the suffering of the world as their own; only in the case of a few, I say, is this knowledge sufficient to bring about the denial of the will. Even with him who approaches this point, it is almost invariably the case that the tolerable condition of his own body, the flattery of the moment, the delusion of hope, and the satisfaction of the will, which is ever presenting itself anew, *i.e.*, lust, is a constant hindrance to the denial of the will, and a constant temptation to the renewed assertion of it. Therefore in this respect all these illusions have been personified as the devil. Thus in most cases the will must be broken by great personal suffering before its self-conquest appears. Then we see the man who has passed through all the increasing degrees of affliction with the most vehement resistance, and is finally brought to the verge of despair, suddenly retire into himself, know himself and the world, change his whole nature, rise above himself and all suffering, as if purified and sanctified by it, in inviolable peace, blessedness, and sublimity, willingly renounce everything he previously desired with all his might, and joyfully embrace death. It is the refined silver of the denial of the will to live that suddenly comes forth from the purifying flame of suffering. It is salvation. Sometimes we see even those who were very wicked purified to this degree by great grief; they have become new beings and are completely changed. Therefore their former misdeeds trouble their consciences no more, yet they willingly atone for them by death, and gladly see the end of the manifestation of that will which is now foreign to them and abhorred by them. The great Goethe has given us a distinct and visible representation of this denial of the will, brought about by great misfortunes

and despair of all deliverance, in his immortal masterpiece "Faust," in the story of the sufferings of Gretchen. I know no parallel to this in poetry. It is a perfect example of the second path that leads to the denial of the will, not, as the first, through the mere knowledge of the sufferings of a whole world which one has voluntarily acquired, but through excessive suffering experienced in one's own person. Many tragedies certainly end by conducting their strong-willed heroes to the point of entire resignation, and then generally the will to live and its manifestation end together, but no representation that is known to me brings what is essential to that change so distinctly before us, free from all that is extraneous, as the part of "Faust" I have referred to.

In actual life we see that those unfortunate persons who have to drink to the dregs the greatest cup of suffering, since when all hope is taken from them they have to face with full consciousness a shameful, violent, and often painful death on the scaffold, are very frequently changed in this way. We must not indeed assume that there is so great a difference between their character and that of most men as their fate would seem to indicate, but must attribute the latter for the most part to circumstances; yet they are guilty and to a considerable degree bad. We see, however, many of them, when they have entirely lost hope, changed in the way referred to. They now show actual goodness and purity of disposition, true abhorrence of doing any act in the least degree bad or unkind. They forgive their enemies, even if it is through them that they innocently suffer; and not with words merely and a sort of hypocritical fear of the judges of the lower world, but in reality and with inward earnestness and no desire for revenge. Indeed, their sufferings and death at last becomes dear to them, for the denial of the will to live has appeared; they often decline the deliverance when it is offered, and die gladly, peacefully, and happily. To them the last secret of life has revealed itself in their excessive pain; the secret that misery and wickedness, sorrow and hate, the sufferer and the inflicter of suffering, however different they may appear to the knowledge which follows the principle of sufficient reason, are in themselves one, the manifestation of that one will to live which objectifies its conflict with itself by means of the *principium individuationis*. They have learned to know both sides in full measure, the badness and the misery; and since at last they see the identity of the two, they reject them both at once; they deny the will to live. In what myths and dogmas they account to their reason for this intuitive and direct

knowledge and for their own change is, as has been said, a matter of no importance.

Matthias Claudius must without doubt have witnessed a change of mind of this description when he wrote the remarkable essay in the “Wandsbecker Boten” (pt. i. p. 115) with the title “Bekehrungsgeschichte des * * *” (“History of the Conversion of * * *”), which concludes thus: “Man’s way of thinking may pass from one point of the periphery to the opposite point, and again back to the former point, if circumstances mark out for him the path. And these changes in a man are really nothing great or interesting, but that *remarkable, catholic, transcendental change* in which the whole circle is irreparably broken up and all the laws of psychology become vain and empty when the coat is stripped from the shoulders, or at least turned outside in, and as it were scales fall from a man’s eyes, is such that every one who has breath in his nostrils forsakes father and mother if he can hear or experience something certain about it.”

The approach of death and hopelessness are in other respects not absolutely necessary for such a purification through suffering. Even without them the knowledge of the contradiction of the will to live with itself can, through great misfortune and pain, force an entrance, and the vanity of all striving become recognised. Hence it has often happened that men who have led a very restless life in the full strain of the passions, kings, heroes, and adventurers, suddenly change, betake themselves to resignation and penance, become hermits or monks. To this class belong all true accounts of conversions; for example, that of Raymond Lully, who had long wooed a fair lady, and was at last admitted to her chamber, anticipating the fulfilment of all his wishes, when she, opening her bodice, showed him her bosom frightfully eaten with cancer. From that moment, as if he had looked into hell, he was changed; he forsook the court of the king of Majorca, and went into the desert to do penance.[88] This conversion is very like that of the Abbé Rancé, which I have briefly related in the 48th chapter of the Supplement. If we consider how in both cases the transition from the pleasure to the horror of life was the occasion of it, this throws some light upon the remarkable fact that it is among the French, the most cheerful, gay, sensuous, and frivolous nation in Europe, that by far the strictest of all monastic orders, the Trappists, arose, was re-established by Rancé after its fall, and has maintained itself to the present day in all its purity and strictness, in spite of revolutions, Church reformations, and encroachments of infidelity.

But a knowledge such as that referred to above of the nature of this existence may leave us again along with the occasion of it and the will to live, and with it the previous character may reappear. Thus we see that the passionate Benvenuto Cellini was changed in this way, once when he was in prison, and again when very ill; but when the suffering passed over, he fell back again into his old state. In general, the denial of the will to live by no means proceeds from suffering with the necessity of an effect from its cause, but the will remains free; for this is indeed the one point at which its freedom appears directly in the phenomenon; hence the astonishment which Asmus expresses so strongly at the "transcendental change." In the case of every suffering, it is always possible to conceive a will which exceeds it in intensity and is therefore unconquered by it. Thus Plato speaks in the "Phædon" of men who up to the moment of their execution feast, drink, and indulge in sensuous pleasure, asserting life even to the death. Shakespeare shows us in Cardinal Beaufort the fearful end of a profligate, who dies full of despair, for no suffering or death can break his will, which is vehement to the extreme of wickedness.[89]

The more intense the will is, the more glaring is the conflict of its manifestation, and thus the greater is the suffering. A world which was the manifestation of a far more intense will to live than this world manifests would produce so much the greater suffering; would thus be a hell.

All suffering, since it is a mortification and a call to resignation, has potentially a sanctifying power. This is the explanation of the fact that every great misfortune or deep pain inspires a certain awe. But the sufferer only really becomes an object of reverence when, surveying the course of his life as a chain of sorrows, or mourning some great and incurable misfortune, he does not really look at the special combination of circumstances which has plunged his own life into suffering, nor stops at the single great misfortune that has befallen him; for in so doing his knowledge still follows the principle of sufficient reason, and clings to the particular phenomenon; he still wills life only not under the conditions which have happened to him; but only then, I say, he is truly worthy of reverence when he raises his glance from the particular to the universal, when he regards his suffering as merely an example of the whole, and for him, since in a moral regard he partakes of genius, one case stands for a thousand, so that the whole of life conceived as essentially suffering brings him to resignation. Therefore it inspires reverence when in Goethe's "Torquato Tasso" the princess speaks

of how her own life and that of her relations has always been sad and joyless, and yet regards the matter from an entirely universal point of view.

A very noble character we always imagine with a certain trace of quiet sadness, which is anything but a constant fretfulness at daily annoyances (this would be an ignoble trait, and lead us to fear a bad disposition), but is a consciousness derived from knowledge of the vanity of all possessions, of the suffering of all life, not merely of his own. But such knowledge may primarily be awakened by the personal experience of suffering, especially some one great sorrow, as a single unfulfilled wish brought Petrarch to that state of resigned sadness concerning the whole of life which appeals to us so pathetically in his works; for the Daphne he pursued had to flee from his hands in order to leave him, instead of herself, the immortal laurel. When through some such great and irrevocable denial of fate the will is to some extent broken, almost nothing else is desired, and the character shows itself mild, just, noble, and resigned. When, finally, grief has no definite object, but extends itself over the whole of life, then it is to a certain extent a going into itself, a withdrawal, a gradual disappearance of the will, whose visible manifestation, the body, it imperceptibly but surely undermines, so that a man feels a certain loosening of his bonds, a mild foretaste of that death which promises to be the abolition at once of the body and of the will. Therefore a secret pleasure accompanies this grief, and it is this, as I believe, which the most melancholy of all nations has called "the joy of grief." But here also lies the danger of *sentimentality*, both in life itself and in the representation of it in poetry; when a man is always mourning and lamenting without courageously rising to resignation. In this way we lose both earth and heaven, and retain merely a watery sentimentality. Only if suffering assumes the form of pure knowledge, and this, acting as a *quieter of the will*, brings about resignation, is it worthy of reverence. In this regard, however, we feel a certain respect at the sight of every great sufferer which is akin to the feeling excited by virtue and nobility of character, and also seems like a reproach of our own happy condition. We cannot help regarding every sorrow, both our own and those of others, as at least a potential advance towards virtue and holiness, and, on the contrary, pleasures and worldly satisfactions as a retrogression from them. This goes so far, that every man who endures a great bodily or mental suffering, indeed every one who merely performs some physical labour which demands the greatest exertion, in the sweat of his brow and with evident

exhaustion, yet with patience and without murmuring, every such man, I say, if we consider him with close attention, appears to us like a sick man who tries a painful cure, and who willingly, and even with satisfaction, endures the suffering it causes him, because he knows that the more he suffers the more the cause of his disease is affected, and that therefore the present suffering is the measure of his cure.

According to what has been said, the denial of the will to live, which is just what is called absolute, entire resignation, or holiness, always proceeds from that quieter of the will which the knowledge of its inner conflict and essential vanity, expressing themselves in the suffering of all living things, becomes. The difference, which we have represented as two paths, consists in whether that knowledge is called up by suffering which is merely and purely *known*, and is freely appropriated by means of the penetration of the *principium individuationis*, or by suffering which is directly *felt* by a man himself. True salvation, deliverance from life and suffering, cannot even be imagined without complete denial of the will. Till then, every one is simply this will itself, whose manifestation is an ephemeral existence, a constantly vain and empty striving, and the world full of suffering we have represented, to which all irrevocably and in like manner belong. For we found above that life is always assured to the will to live, and its one real form is the present, from which they can never escape, since birth and death reign in the phenomenal world. The Indian mythus expresses this by saying "they are born again." The great ethical difference of character means this, that the bad man is infinitely far from the attainment of the knowledge from which the denial of the will proceeds, and therefore he is in truth *actually* exposed to all the miseries which appear in life as *possible*; for even the present fortunate condition of his personality is merely a phenomenon produced by the *principium individuationis*, and a delusion of Mâyâ, the happy dream of a beggar. The sufferings which in the vehemence and ardour of his will he inflicts upon others are the measure of the suffering, the experience of which in his own person cannot break his will, and plainly lead it to the denial of itself. All true and pure love, on the other hand, and even all free justice, proceed from the penetration of the *principium individuationis*, which, if it appears with its full power, results in perfect sanctification and salvation, the phenomenon of which is the state of resignation described above, the unbroken peace which accompanies it, and the greatest delight in death.[90]

§ 69. Suicide, the actual doing away with the individual manifestation of will, differs most widely from the denial of the will to live, which is the single outstanding act of free-will in the manifestation, and is therefore, as Asmus calls it, the transcendental change. This last has been fully considered in the course of our work. Far from being denial of the will, suicide is a phenomenon of strong assertion of will; for the essence of negation lies in this, that the joys of life are shunned, not its sorrows. The suicide wills life, and is only dissatisfied with the conditions under which it has presented itself to him. He therefore by no means surrenders the will to live, but only life, in that he destroys the individual manifestation. He wills life — wills the unrestricted existence and assertion of the body; but the complication of circumstances does not allow this, and there results for him great suffering. The very will to live finds itself so much hampered in this particular manifestation that it cannot put forth its energies. It therefore comes to such a determination as is in conformity with its own nature, which lies outside the conditions of the principle of sufficient reason, and to which, therefore, all particular manifestations are alike indifferent, inasmuch as it itself remains unaffected by all appearing and passing away, and is the inner life of all things; for that firm inward assurance by reason of which we all live free from the constant dread of death, the assurance that a phenomenal existence can never be wanting to the will, supports our action even in the case of suicide. Thus the will to live appears just as much in suicide (Siva) as in the satisfaction of self-preservation (Vishnu) and in the sensual pleasure of procreation (Brahma). This is the inner meaning of the unity of the Trimurtis, which is embodied in its entirety in every human being, though in time it raises now one, now another, of its three heads. Suicide stands in the same relation to the denial of the will as the individual thing does to the Idea. The suicide denies only the individual, not the species. We have already seen that as life is always assured to the will to live, and as sorrow is inseparable from life, suicide, the wilful destruction of the single phenomenal existence, is a vain and foolish act; for the thing-in-itself remains unaffected by it, even as the rainbow endures however fast the drops which support it for the moment may change. But, more than this, it is also the masterpiece of Mâyâ, as the most flagrant example of the contradiction of the will to live with itself. As we found this contradiction in the case of the lowest manifestations of will, in the permanent struggle of all the forces of nature, and of all organic individuals for matter and time

and space; and as we saw this antagonism come ever more to the front with terrible distinctness in the ascending grades of the objectification of the will, so at last in the highest grade, the Idea of man, it reaches the point at which, not only the individuals which express the same Idea extirpate each other, but even the same individual declares war against itself. The vehemence with which it wills life, and revolts against what hinders it, namely, suffering, brings it to the point of destroying itself; so that the individual will, by its own act, puts an end to that body which is merely its particular visible expression, rather than permit suffering to break the will. Just because the suicide cannot give up willing, he gives up living. The will asserts itself here even in putting an end to its own manifestation, because it can no longer assert itself otherwise. As, however, it was just the suffering which it so shuns that was able, as mortification of the will, to bring it to the denial of itself, and hence to freedom, so in this respect the suicide is like a sick man, who, after a painful operation which would entirely cure him has been begun, will not allow it to be completed, but prefers to retain his disease. Suffering approaches and reveals itself as the possibility of the denial of will; but the will rejects it, in that it destroys the body, the manifestation of itself, in order that it may remain unbroken. This is the reason why almost all ethical teachers, whether philosophical or religious, condemn suicide, although they themselves can only give far-fetched sophistical reasons for their opinion. But if a human being was ever restrained from committing suicide by purely moral motives, the inmost meaning of this self-conquest (in whatever ideas his reason may have clothed it) was this: "I will not shun suffering, in order that it may help to put an end to the will to live, whose manifestation is so wretched, by so strengthening the knowledge of the real nature of the world which is already beginning to dawn upon me, that it may become the final quieter of my will, and may free me for ever."

It is well known that from time to time cases occur in which the act of suicide extends to the children. The father first kills the children he loves, and then himself. Now, if we consider that conscience, religion, and all influencing ideas teach him to look upon murder as the greatest of crimes, and that, in spite of this, he yet commits it, in the hour of his own death, and when he is altogether uninfluenced by any egotistical motive, such a deed can only be explained in the following manner: in this case, the will of the individual, the father, recognises itself immediately in the children, though

involved in the delusion of mistaking the appearance for the true nature; and as he is at the same time deeply impressed with the knowledge of the misery of all life, he now thinks to put an end to the inner nature itself, along with the appearance, and thus seeks to deliver from existence and its misery both himself and his children, in whom he discerns himself as living again. It would be an error precisely analogous to this to suppose that one may reach the same end as is attained through voluntary chastity by frustrating the aim of nature in fecundation; or indeed if, in consideration of the unendurable suffering of life, parents were to use means for the destruction of their new-born children, instead of doing everything possible to ensure life to that which is struggling into it. For if the will to live is there, as it is the only metaphysical reality, or the thing-in-itself, no physical force can break it, but can only destroy its manifestation at this place and time. It itself can never be transcended except through knowledge. Thus the only way of salvation is, that the will shall manifest itself unrestrictedly, in order that in this individual manifestation it may come to apprehend its own nature. Only as the result of this knowledge can the will transcend itself, and thereby end the suffering which is inseparable from its manifestation. It is quite impossible to accomplish this end by physical force, as by destroying the germ, or by killing the new-born child, or by committing suicide. Nature guides the will to the light, just because it is only in the light that it can work out its salvation. Therefore the aims of Nature are to be promoted in every way as soon as the will to live, which is its inner being, has determined itself.

There is a species of suicide which seems to be quite distinct from the common kind, though its occurrence has perhaps not yet been fully established. It is starvation, voluntarily chosen on the ground of extreme asceticism. All instances of it, however, have been accompanied and obscured by much religious fanaticism, and even superstition. Yet it seems that the absolute denial of will may reach the point at which the will shall be wanting to take the necessary nourishment for the support of the natural life. This kind of suicide is so far from being the result of the will to live, that such a completely resigned ascetic only ceases to live because he has already altogether ceased to will. No other death than that by starvation is in this case conceivable (unless it were the result of some special superstition); for the intention to cut short the torment would itself be a stage in the assertion of will. The dogmas which satisfy the reason of such a penitent

delude him with the idea that a being of a higher nature has inculcated the fasting to which his own inner tendency drives him. Old examples of this may be found in the "Breslauer Sammlung von Natur- und Medicin-Geschichten," September 1799, p. 363; in Bayle's "Nouvelles de la République des Lettres," February 1685, p. 189; in Zimmermann, "Ueber die Einsamkeit," vol. i. p. 182; in the "Histoire de l'Académie des Sciences" for 1764, an account by Houttuyn, which is quoted in the "Sammlung für praktische Aerzte," vol. i. p. 69. More recent accounts may be found in Hufeland's "Journal für praktische Heilkunde," vol. x. p. 181, and vol. xlviii. p. 95; also in Nasse's "Zeitschrift für psychische Aerzte," 1819, part iii. p. 460; and in the "Edinburgh Medical and Surgical Journal," 1809, vol. v. p. 319. In the year 1833 all the papers announced that the English historian, Dr. Lingard, had died in January at Dover of voluntary starvation; according to later accounts, it was not he himself, but a relation of his who died. Still in these accounts the persons were generally described as insane, and it is no longer possible to find out how far this was the case. But I will give here a more recent case of this kind, if it were only to ensure the preservation of one of the rare instances of this striking and extraordinary phenomenon of human nature, which, to all appearance at any rate, belongs to the category to which I wish to assign it and could hardly be explained in any other way. This case is reported in the "Nürnberger Correspondenten" of the 29th July 1813, in these words:— "We hear from Bern that in a thick wood near Thurnen a hut has been discovered in which was lying the body of a man who had been dead about a month. His clothes gave little or no clue to his social position. Two very fine shirts lay beside him. The most important article, however, was a Bible interleaved with white paper, part of which had been written upon by the deceased. In this writing he gives the date of his departure from home (but does not mention where his home was). He then says that he was driven by the Spirit of God into the wilderness to pray and fast. During his journey he had fasted seven days and then he had again taken food. After this he had begun again to fast, and continued to do so for the same number of days as before. From this point we find each day marked with a stroke, and of these there are five, at the expiration of which the pilgrim presumably died. There was further found a letter to a clergyman about a sermon which the deceased heard him preach, but the letter was not addressed." Between this voluntary death arising from extreme asceticism and the common suicide resulting from despair there

may be various intermediate species and combinations, though this is hard to find out. But human nature has depths, obscurities, and perplexities, the analysis and elucidation of which is a matter of the very greatest difficulty.

§ 70. It might be supposed that the entire exposition (now terminated) of that which I call the denial of the will is irreconcilable with the earlier explanation of necessity, which belongs just as much to motivation as to every other form of the principle of sufficient reason, and according to which, motives, like all causes, are only occasional causes, upon which the character unfolds its nature and reveals it with the necessity of a natural law, on account of which we absolutely denied freedom as *liberum arbitrium indifferentiæ*. But far from suppressing this here, I would call it to mind. In truth, real freedom, *i.e.*, independence of the principle of sufficient reason, belongs to the will only as a thing-in-itself, not to its manifestation, whose essential form is everywhere the principle of sufficient reason, the element or sphere of necessity. But the one case in which that freedom can become directly visible in the manifestation is that in which it makes an end of what manifests itself, and because the mere manifestation, as a link in the chain of causes, the living body in time, which contains only phenomena, still continues to exist, the will which manifests itself through this phenomenon then stands in contradiction to it, for it denies what the phenomenon expresses. In such a case the organs of generation, for example, as the visible form of the sexual impulse, are there and in health; but yet, in the inmost consciousness, no sensual gratification is desired; and although the whole body is only the visible expression of the will to live, yet the motives which correspond to this will no longer act; indeed, the dissolution of the body, the end of the individual, and in this way the greatest check to the natural will, is welcome and desired. Now, the contradiction between our assertions of the necessity of the determination of the will by motives, in accordance with the character, on the one hand, and of the possibility of the entire suppression of the will whereby the motives become powerless, on the other hand, is only the repetition in the reflection of philosophy of this *real* contradiction which arises from the direct encroachment of the freedom of the will-in-itself, which knows no necessity, into the sphere of the necessity of its manifestation. But the key to the solution of these contradictions lies in the fact that the state in which the character is withdrawn from the power of motives does not proceed directly from the will, but from a changed form of knowledge. So long as the knowledge is

merely that which is involved in the *principium individuationis* and exclusively follows the principle of sufficient reason, the strength of the motives is irresistible. But when the *principium individuationis* is seen through, when the Ideas, and indeed the inner nature of the thing-in-itself, as the same will in all, are directly recognised, and from this knowledge an universal quieter of volition arises, then the particular motives become ineffective, because the kind of knowledge which corresponds to them is obscured and thrown into the background by quite another kind. Therefore the character can never partially change, but must, with the consistency of a law of Nature, carry out in the particular the will which it manifests as a whole. But this whole, the character itself, may be completely suppressed or abolished through the change of knowledge referred to above. It is this suppression or abolition which Asmus, as quoted above, marvels at and denotes the "catholic, transcendental change;" and in the Christian Church it has very aptly been called the *new birth*, and the knowledge from which it springs, the *work of grace*. Therefore it is not a question of a change, but of an entire suppression of the character; and hence it arises that, however different the characters which experience the suppression may have been before it, after it they show a great similarity in their conduct, though every one still speaks very differently according to his conceptions and dogmas.

In this sense, then, the old philosophical doctrine of the freedom of the will, which has constantly been contested and constantly maintained, is not without ground, and the dogma of the Church of the work of grace and the new birth is not without meaning and significance. But we now unexpectedly see both united in one, and we can also now understand in what sense the excellent Malebranche could say, "*La liberté est un mystère*," and was right. For precisely what the Christian mystics call *the work of grace* and *the new birth*, is for us the single direct expression of *the freedom of the will*. It only appears if the will, having attained to a knowledge of its own real nature, receives from this a *quieter*, by means of which the motives are deprived of their effect, which belongs to the province of another kind of knowledge, the objects of which are merely phenomena. The possibility of the freedom which thus expresses itself is the greatest prerogative of man, which is for ever wanting to the brute, because the condition of it is the deliberation of reason, which enables him to survey the whole of life independent of the impression of the present. The brute is entirely without the possibility of freedom, as, indeed, it is without the

possibility of a proper or deliberate choice following upon a completed conflict of motives, which for this purpose would have to be abstract ideas. Therefore with the same necessity with which the stone falls to the earth, the hungry wolf buries its fangs in the flesh of its prey, without the possibility of the knowledge that it is itself the destroyed as well as the destroyer. *Necessity is the kingdom of nature; freedom is the kingdom of grace.*

Now because, as we have seen, that *self-suppression of the will* proceeds from knowledge, and all knowledge is involuntary, that denial of will also, that entrance into freedom, cannot be forcibly attained to by intention or design, but proceeds from the inmost relation of knowing and volition in the man, and therefore comes suddenly, as if spontaneously from without. This is why the Church has called it *the work of grace*; and that it still regards it as independent of the acceptance of grace corresponds to the fact that the effect of the quieter is finally a free act of will. And because, in consequence of such a work of grace, the whole nature of man is changed and reversed from its foundation, so that he no longer wills anything of all that he previously willed so intensely, so that it is as if a new man actually took the place of the old, the Church has called this consequence of the work of grace the *new birth*. For what it calls the *natural man*, to which it denies all capacity for good, is just the will to live, which must be denied if deliverance from an existence such as ours is to be attained. Behind our existence lies something else, which is only accessible to us if we have shaken off this world.

Having regard, not to the individuals according to the principle of sufficient reason, but to the Idea of man in its unity, Christian theology symbolises *nature*, the *assertion of the will to live* in Adam, whose sin, inherited by us, *i.e.*, our unity with him in the Idea, which is represented in time by the bond of procreation, makes us all partakers of suffering and eternal death. On the other hand, it symbolises *grace*, the *denial of the will*, *salvation*, in the incarnate God, who, as free from all sin, that is, from all willing of life, cannot, like us, have proceeded from the most pronounced assertion of the will, nor can he, like us, have a body which is through and through simply concrete will, manifestation of the will; but born of a pure virgin, he has only a phantom body. This last is the doctrine of the Docetæ, *i.e.*, certain Church Fathers, who in this respect are very consistent. It is especially taught by Apelles, against whom and his followers Tertullian

wrote. But even Augustine comments thus on the passage, Rom. viii. 3, "God sent his Son in the likeness of sinful flesh:" "*Non enim caro peccati erat, quæ non de carnali delectatione nata erat: sed tamen inerat ei similitudo carnis peccati, quia mortalis caro erat*" (Liber 83, *quæst. qu.* 66). He also teaches in his work entitled "*Opus Imperfectum*," i. 47, that inherited sin is both sin and punishment at once. It is already present in new-born children, but only shows itself if they grow up. Yet the origin of this sin is to be referred to the will of the sinner. This sinner was Adam, but we all existed in him; Adam became miserable, and in him we have all become miserable. Certainly the doctrine of original sin (assertion of the will) and of salvation (denial of the will) is the great truth which constitutes the essence of Christianity, while most of what remains is only the clothing of it, the husk or accessories. Therefore Jesus Christ ought always to be conceived in the universal, as the symbol or personification of the denial of the will to live, but never as an individual, whether according to his mythical history given in the Gospels, or according to the probably true history which lies at the foundation of this. For neither the one nor the other will easily satisfy us entirely. It is merely the vehicle of that conception for the people, who always demand something actual. That in recent times Christianity has forgotten its true significance, and degenerated into dull optimism, does not concern us here.

It is further an original and evangelical doctrine of Christianity — which Augustine, with the consent of the leaders of the Church, defended against the platitudes of the Pelagians, and which it was the principal aim of Luther's endeavour to purify from error and re-establish, as he expressly declares in his book, "*De Servo Arbitrio*," — the doctrine that *the will is not free*, but originally subject to the inclination to evil. Therefore according to this doctrine the deeds of the will are always sinful and imperfect, and can never fully satisfy justice; and, finally, these works can never save us, but faith alone, a faith which itself does not spring from resolution and free will, but from the work of grace, without our co-operation, comes to us as from without.

Not only the dogmas referred to before, but also this last genuine evangelical dogma belongs to those which at the present day an ignorant and dull opinion rejects as absurd or hides. For, in spite of Augustine and Luther, it adheres to the vulgar Pelagianism, which the rationalism of the day really is, and treats as antiquated those deeply significant dogmas which

are peculiar and essential to Christianity in the strictest sense; while, on the other hand, it holds fast and regards as the principal matter only the dogma that originates in Judaism, and has been retained from it, and is merely historically connected with Christianity.[91] We, however, recognise in the doctrine referred to above the truth completely agreeing with the result of our own investigations. We see that true virtue and holiness of disposition have their origin not in deliberate choice (works), but in knowledge (faith); just as we have in like manner developed it from our leading thought. If it were works, which spring from motives and deliberate intention, that led to salvation, then, however one may turn it, virtue would always be a prudent, methodical, far-seeing egoism. But the faith to which the Christian Church promises salvation is this: that as through the fall of the first man we are all partakers of sin and subject to death and perdition, through the divine substitute, through grace and the taking upon himself of our fearful guilt, we are all saved, without any merit of our own (of the person); since that which can proceed from the intentional (determined by motives) action of the person, works, can never justify us, from its very nature, just because it is *intentional*, action induced by motives, *opus operatum*. Thus in this faith there is implied, first of all, that our condition is originally and essentially an incurable one, from which we need *salvation*; then, that we ourselves essentially belong to evil, and are so firmly bound to it that our works according to law and precept, *i.e.*, according to motives, can never satisfy justice nor save us; but salvation is only obtained through faith, *i.e.*, through a changed mode of knowing, and this faith can only come through grace, thus as from without. This means that the salvation is one which is quite foreign to our person, and points to a denial and surrender of this person necessary to salvation. Works, the result of the law as such, can never justify, because they are always action following upon motives. Luther demands (in his book "*De Libertate Christiana*") that after the entrance of faith the good works shall proceed from it entirely of themselves, as symptoms, as fruits of it; yet by no means as constituting in themselves a claim to merit, justification, or reward, but taking place quite voluntarily and gratuitously. So we also hold that from the ever-clearer penetration of the *principium individuationis* proceeds, first, merely free justice, then love, extending to the complete abolition of egoism, and finally resignation or denial of the will.

I have here introduced these dogmas of Christian theology, which in themselves are foreign to philosophy, merely for the purpose of showing that the ethical doctrine which proceeds from our whole investigation, and is in complete agreement and connection with all its parts, although new and unprecedented in its expression, is by no means so in its real nature, but fully agrees with the Christian dogmas properly so called, and indeed, as regards its essence, was contained and present in them. It also agrees quite as accurately with the doctrines and ethical teachings of the sacred books of India, which in their turn are presented in quite different forms. At the same time the calling to mind of the dogmas of the Christian Church serves to explain and illustrate the apparent contradiction between the necessity of all expressions of character when motives are presented (the kingdom of Nature) on the one hand, and the freedom of the will in itself, to deny itself, and abolish the character with all the necessity of the motives based upon it (the kingdom of grace) on the other hand.

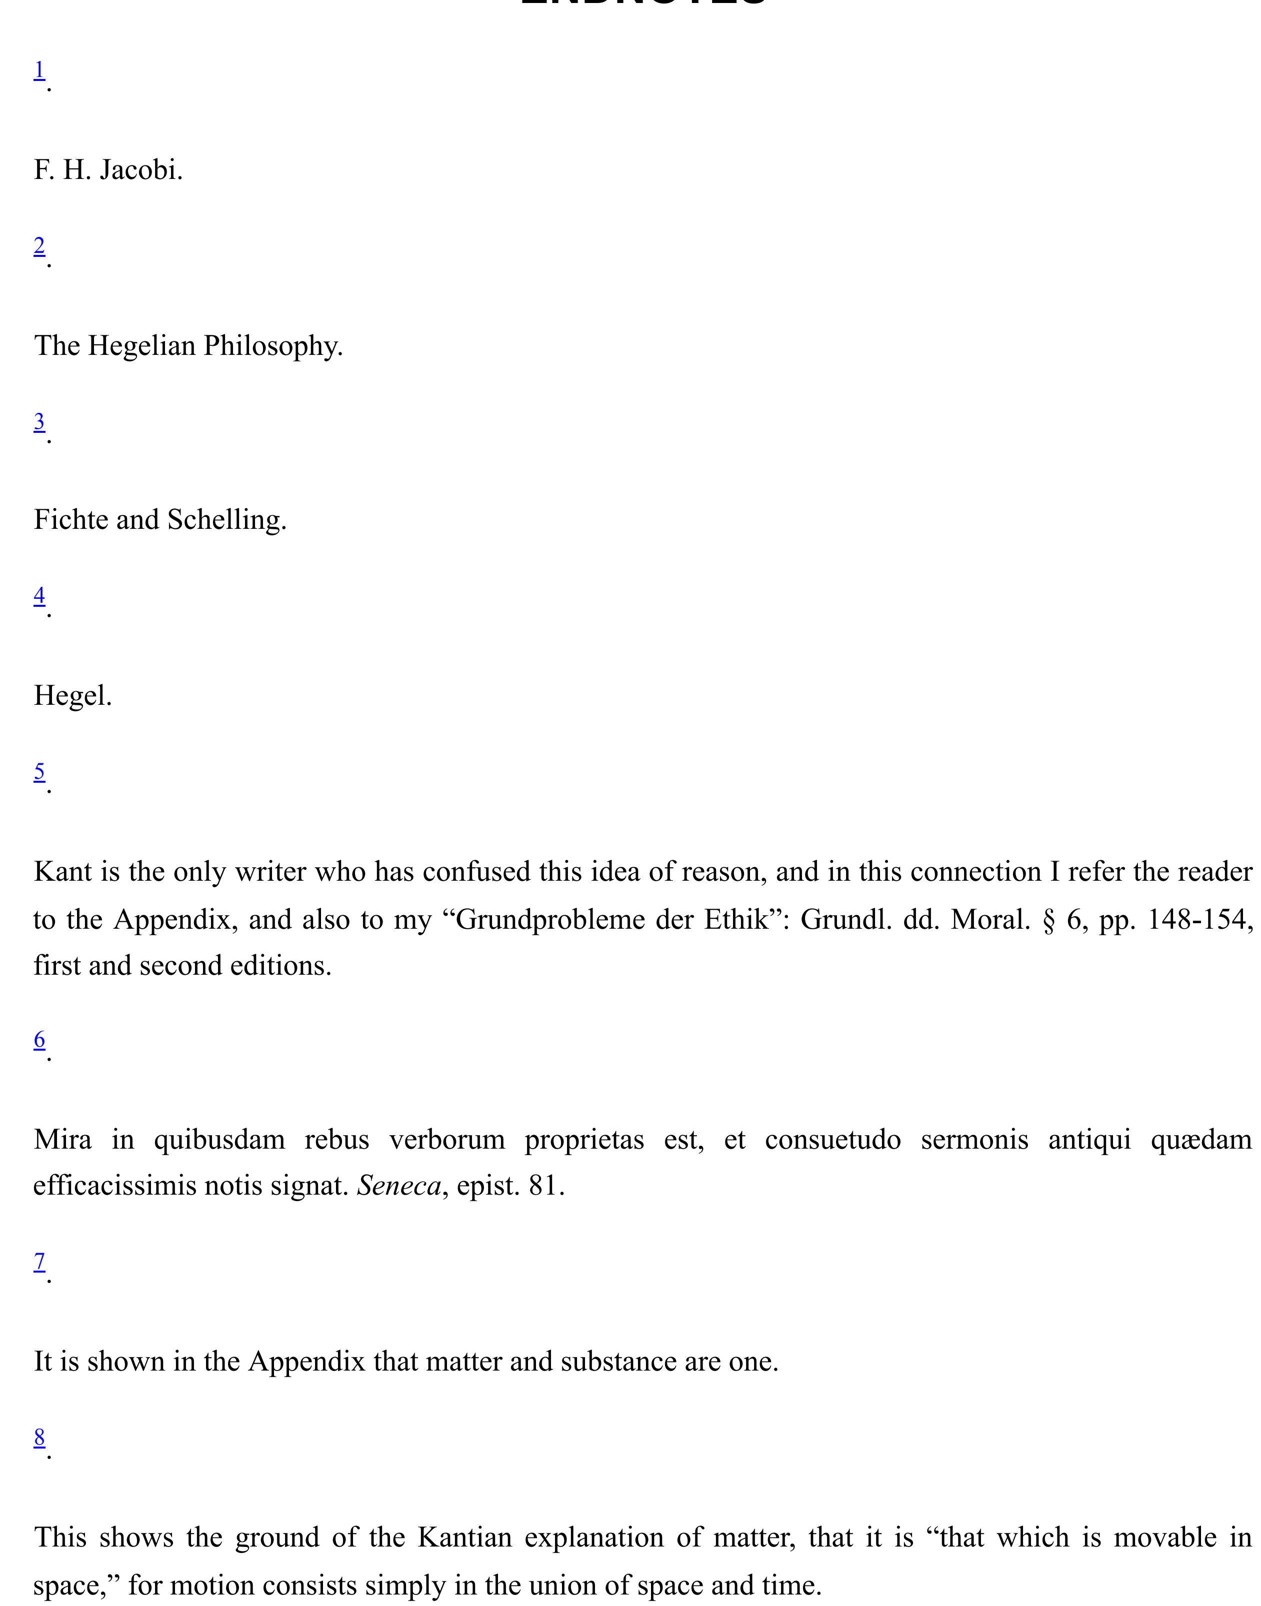
§ 71. I now end the general account of ethics, and with it the whole development of that one thought which it has been my object to impart; and I by no means desire to conceal here an objection which concerns this last part of my exposition, but rather to point out that it lies in the nature of the question, and that it is quite impossible to remove it. It is this, that after our investigation has brought us to the point at which we have before our eyes perfect holiness, the denial and surrender of all volition, and thus the deliverance from a world whose whole existence we have found to be suffering, this appears to us as a passing away into empty nothingness.

On this I must first remark, that the conception of nothing is essentially relative, and always refers to a definite something which it negatives. This quality has been attributed (by Kant) merely to the *nihil privativum*, which is indicated by - as opposed to +, which -, from an opposite point of view, might become +, and in opposition to this *nihil privativum* the *nihil negativum* has been set up, which would in every reference be nothing, and as an example of this the logical contradiction which does away with itself has been given. But more closely considered, no absolute nothing, no proper *nihil negativum* is even thinkable; but everything of this kind, when considered from a higher standpoint or subsumed under a wider concept, is always merely a *nihil privativum*. Every nothing is thought as such only in relation to something, and presupposes this relation, and thus also this something. Even a logical contradiction is only a relative nothing. It is no

thought of the reason, but it is not on that account an absolute nothing; for it is a combination of words; it is an example of the unthinkable, which is necessary in logic in order to prove the laws of thought. Therefore if for this end such an example is sought, we will stick to the nonsense as the positive which we are in search of, and pass over the sense as the negative. Thus every *nihil negativum*, if subordinated to a higher concept, will appear as a mere *nihil privativum* or relative nothing, which can, moreover, always exchange signs with what it negatives, so that that would then be thought as negation, and it itself as assertion. This also agrees with the result of the difficult dialectical investigation of the meaning of nothing which Plato gives in the "Sophist" (pp. 277-287): Την του ἑτερου φυσιν αποδειξαντες ουσαν τε, και κατακεκερματισμενην επι παντα τα οντα προς αλληλα, το προς το ον ἑκαστου μοριου αυτης αντιτιθεμενον, ετολμησαμεν ειπειν, ὡς αυτο τουτο εστιν οντως το μη ον (*Cum enim ostenderemus, alterius ipsius naturam esse perque omnia entia divisam atque dispersam in vicem; tunc partem ejus oppositam ei, quod cujusque ens est, esse ipsum revera non ens asseruimus*).

That which is generally received as positive, which we call the real, and the negation of which the concept nothing in its most general significance expresses, is just the world as idea, which I have shown to be the objectivity and mirror of the will. Moreover, we ourselves are just this will and this world, and to them belongs the idea in general, as one aspect of them. The form of the idea is space and time, therefore for this point of view all that is real must be in some place and at some time. Denial, abolition, conversion of the will, is also the abolition and the vanishing of the world, its mirror. If we no longer perceive it in this mirror, we ask in vain where it has gone, and then, because it has no longer any where and when, complain that it has vanished into nothing.

A reversed point of view, if it were possible for us, would reverse the signs and show the real for us as nothing, and that nothing as the real. But as long as we ourselves are the will to live, this last — nothing as the real — can only be known and signified by us negatively, because the old saying of Empedocles, that like can only be known by like, deprives us here of all knowledge, as, conversely, upon it finally rests the possibility of all our actual knowledge, *i.e.*, the world as idea; for the world is the self-knowledge of the will.



If, however, it should be absolutely insisted upon that in some way or other a positive knowledge should be attained of that which philosophy can only express negatively as the denial of the will, there would be nothing for it but to refer to that state which all those who have attained to complete denial of the will have experienced, and which has been variously denoted by the names ecstasy, rapture, illumination, union with God, and so forth; a state, however, which cannot properly be called knowledge, because it has not the form of subject and object, and is, moreover, only attainable in one's own experience and cannot be further communicated.

We, however, who consistently occupy the standpoint of philosophy, must be satisfied here with negative knowledge, content to have reached the utmost limit of the positive. We have recognised the inmost nature of the world as will, and all its phenomena as only the objectivity of will; and we have followed this objectivity from the unconscious working of obscure forces of Nature up to the completely conscious action of man. Therefore we shall by no means evade the consequence, that with the free denial, the surrender of the will, all those phenomena are also abolished; that constant strain and effort without end and without rest at all the grades of objectivity, in which and through which the world consists; the multifarious forms succeeding each other in gradation; the whole manifestation of the will; and, finally, also the universal forms of this manifestation, time and space, and also its last fundamental form, subject and object; all are abolished. No will: no idea, no world.

Before us there is certainly only nothingness. But that which resists this passing into nothing, our nature, is indeed just the will to live, which we ourselves are as it is our world. That we abhor annihilation so greatly, is simply another expression of the fact that we so strenuously will life, and are nothing but this will, and know nothing besides it. But if we turn our glance from our own needy and embarrassed condition to those who have overcome the world, in whom the will, having attained to perfect self-knowledge, found itself again in all, and then freely denied itself, and who then merely wait to see the last trace of it vanish with the body which it animates; then, instead of the restless striving and effort, instead of the constant transition from wish to fruition, and from joy to sorrow, instead of the never-satisfied and never-dying hope which constitutes the life of the man who wills, we shall see that peace which is above all reason, that perfect calm of the spirit, that deep rest, that inviolable confidence and

serenity, the mere reflection of which in the countenance, as Raphael and Correggio have represented it, is an entire and certain gospel; only knowledge remains, the will has vanished. We look with deep and painful longing upon this state, beside which the misery and wretchedness of our own is brought out clearly by the contrast. Yet this is the only consideration which can afford us lasting consolation, when, on the one hand, we have recognised incurable suffering and endless misery as essential to the manifestation of will, the world; and, on the other hand, see the world pass away with the abolition of will, and retain before us only empty nothingness. Thus, in this way, by contemplation of the life and conduct of saints, whom it is certainly rarely granted us to meet with in our own experience, but who are brought before our eyes by their written history, and, with the stamp of inner truth, by art, we must banish the dark impression of that nothingness which we discern behind all virtue and holiness as their final goal, and which we fear as children fear the dark; we must not even evade it like the Indians, through myths and meaningless words, such as reabsorption in Brahma or the Nirvana of the Buddhists. Rather do we freely acknowledge that what remains after the entire abolition of will is for all those who are still full of will certainly nothing; but, conversely, to those in whom the will has turned and has denied itself, this our world, which is so real, with all its suns and milky-ways — is nothing.[92]

ENDNOTES

The Hegelian Philosophy.

3.

Fichte and Schelling.

4.

Hegel.

5.

Kant is the only writer who has confused this idea of reason, and in this connection I refer the reader to the Appendix, and also to my "Grundprobleme der Ethik": Grundl. dd. Moral. § 6, pp. 148-154, first and second editions.

6.

Mira in quibusdam rebus verborum proprietas est, et consuetudo sermonis antiqui quædam efficacissimis notis signat. *Seneca*, epist. 81.

7.

It is shown in the Appendix that matter and substance are one.

8.

This shows the ground of the Kantian explanation of matter, that it is "that which is movable in space," for motion consists simply in the union of space and time.

9.

Not, as Kant holds, from the knowledge of time, as will be explained in the Appendix.

10.

On this see "The Fourfold Root of the Principle of Sufficient Reason," § 49.

11.

The first four chapters of the first of the supplementary books belong to these seven paragraphs.

12.

Compare with this paragraph §§ 26 and 27 of the third edition of the essay on the principle of sufficient reason.

16.

I am therefore of opinion that a science of physiognomy cannot, with certainty, go further than to lay down a few quite general rules. For example, the intellectual qualities are to be read in the forehead and the eyes; the moral qualities, the expression of will, in the mouth and lower part of the face. The forehead and the eyes interpret each other; either of them seen alone can only be half understood. Genius is never without a high, broad, finely-arched brow; but such a brow often occurs where there is no genius. A clever-looking person may the more certainly be judged to be so the uglier the face is; and a stupid-looking person may the more certainly be judged to be stupid the more beautiful the face

is; for beauty, as the approximation to the type of humanity, carries in and for itself the expression of mental clearness; the opposite is the case with ugliness, and so forth.

21.

The reader must not think here of Kant's misuse of these Greek terms, which is condemned in the Appendix.

22.

Spinoza, who always boasts that he proceeds *more geometrico*, has actually done so more than he himself was aware. For what he knew with certainty and decision from the immediate, perceptive apprehension of the nature of the world, he seeks to demonstrate logically without reference to this knowledge. He only arrives at the intended and predetermined result by starting from arbitrary concepts framed by himself (*substantia causa sui*, &c.), and in the demonstrations he allows himself all the freedom of choice for which the nature of the wide concept-spheres afford such convenient opportunity. That his doctrine is true and excellent is therefore in his case, as in that of geometry, quite independent of the demonstrations of it. Cf. ch. 13 of supplementary volume.

23.

Cf. Ch. 17 of Supplement.

Omnes perturbationes judicio censent fieri et opinione. Cic. Tusc., 4, 6. Ταρασσει τους ανθρωπους ου τα πραγματα, αλλα τα περι των πραγματων δογματα (Perturbant homines non res ipsæ, sed de rebus opiniones). Epictet., c. v.

25.

Τουτο γαρ εστι το αιτιον τοις ανθρωποις παντων των κακων, το τας προληψεις τας κοινας μη δυνασθαι εφαρμοξειν ταις επι μερους (Hæc est causa mortalibus omnium malorum, non posse communes notiones aptare singularibus). Epict. dissert., ii., 26.

26.

Cf. Ch. 16 of Supplement.

27.

Cf. Ch. xviii. of the Supplement.

28.

We can thus by no means agree with Bacon if he (De Augm. Scient., L. iv. in fine.) thinks that all mechanical and physical movement of bodies has always been preceded by perception in these bodies; though a glimmering of truth lies at the bottom of this false proposition. This is also the case with Kepler's opinion, expressed in his essay *De Planeta Martis*, that the planets must have knowledge in order to keep their elliptical courses so correctly, and to regulate the velocity of their motion so that the triangle of the plane of their course always remains proportional to the time in which they pass through its base.

29.

35.

On the 16th of September 1840, at a lecture upon Egyptian Archæology delivered by Mr. Pettigrew at the Literary and Scientific Institute of London, he showed some corns of wheat which Sir G. Wilkinson had found in a grave at Thebes, in which they must have lain for three thousand years. They were found in an hermetically sealed vase. Mr. Pettigrew had sowed twelve grains, and obtained a plant which grew five feet high, and the seeds of which were now quite ripe. — *Times*, 21st September 1840. In the same way in 1830 Mr. Haulton produced in the Medical Botanical Society of London a bulbous root which was found in the hand of an Egyptian mummy, in which it was probably put in observance of some religious rite, and which must have been at least two thousand years old. He had planted it in a flower-pot, in which it grew up and flourished. This is quoted from the Medical Journal of 1830 in the Journal of the Royal Institute of Great Britain, October 1830, p. 196.— "In the garden of Mr. Grimstone of the Herbarium, Highgate, London, is a pea in full fruit, which has sprung from a pea that Mr. Pettigrew and the officials of the British Museum took out of a vase which had been found in an Egyptian sarcophagus, where it must have

lain 2844 years." — *Times*, 16th August 1844. Indeed, the living toads found in limestone lead to the conclusion that even animal life is capable of such a suspension for thousands of years, if this is begun in the dormant period and maintained by special circumstances.

36.

Cf. Chap. xxii. of the Supplement, and also my work "Ueber den Willen in der Natur," p. 54 *et seq.*, and pp. 70-79 of the first edition, or p. 46 *et seq.*, and pp. 63-72 of the second, or p. 48 *et seq.*, and pp. 69-77 of the third edition.

37.

The Scholastics therefore said very truly: *Causa finalis movet non secundum suum esse reale, sed secundum esse cognitum.* Cf. Suarez, Disp. Metaph. disp. xxiii., sec. 7 and 8.

Cf. Chap. xxviii. of the Supplement.

44.

F. H. Jacobi.

45.

See for example, “Immanuel Kant, a Reminiscence, by Fr. Bouterweck,” pg. 49, and Buhle’s “History of Philosophy,” vol. vi. pp. 802-815 and 823.

46.

Cf. Chap. xxix. of Supplement.

47.

I also recommend the perusal of what Spinoza says in his Ethics (Book II., Prop. 40, Schol. 2, and Book V., Props. 25-38), concerning the *cognitio tertii generis, sive intuitiva*, in illustration of the kind of knowledge we are considering, and very specially Prop. 29, Schol.; prop. 36, Schol., and Prop. 38, Demonst. et Schol.

48.

Cf. Chap. xxx. of the Supplement.

49.

This last sentence cannot be understood without some acquaintance with the next book.

50.

Cf. Chap. xxxi. of the Supplement.

51.

I am all the more delighted and astonished, forty years after I so timidly and hesitatingly advanced this thought, to discover that it has already been expressed by St. Augustine: *Arbusta formas suas varias, quibus mundi hujus visibilis structura formosa est, sentiendas sensibus praebent; ut, pro eo quod* nosse *non possunt, quasi* innotescere *velle videantur*. — *De civ. Dei, xi.* 27.

52.

Cf. Chap. 35 of Supplement.

53.

Jakob Böhm in his book, "de Signatura Rerum," ch. i., § 13-15, says, "There is nothing in nature that does not manifest its internal form externally; for the internal continually labours to manifest itself.... Everything has its language by which to reveal itself.... And this is the language of nature when everything speaks out of its own property, and continually manifests and declares itself, ... for each thing reveals its mother, which thus gives *the essence and the will* to the form."

54.

The last sentence is the German of the *il n'y a que l'esprit qui sente l'esprit*, of Helvetius. In the first edition there was no occasion to point this out, but since then the age has become so degraded and ignorant through the stupefying influence of the Hegelian sophistry, that some might quite likely say that an antithesis was intended here between "spirit and nature." I am therefore obliged to guard myself in express terms against the suspicion of such vulgar sophisms.

55.

This digression is worked out more fully in the 36th Chapter of the Supplement.

56.

In order to understand this passage it is necessary to have read the whole of the next book.

57.

Apparent rari, nantes in gurgite vasto.

58.

Cf. Ch. xxxiv. of Supplement.

59.

It is scarcely necessary to say that wherever I speak of poets I refer exclusively to that rare phenomenon the great true poet. I mean no one else; least of all that dull insipid tribe, the mediocre poets, rhymsters, and inventors of fables, that flourishes so luxuriantly at the present day in Germany. They ought rather to have the words shouted in their ears unceasingly from all sides —

Mediocribus esse poëtis

Non homines, non Dî, non concessere columnæ.

It is worthy of serious consideration what an amount of time — both their own and other people's — and paper is lost by this swarm of mediocre poets, and how injurious is their influence. For the public always seizes on what is new, and has naturally a greater proneness to what is perverse and dull as akin to itself. Therefore these works of the mediocre poets draw it away and hold it back from the true masterpieces and the education they afford, and thus working in direct antagonism to the benign influence of genius, they ruin taste more and more, and retard the progress of the age. Such poets should therefore be scourged with criticism and satire without indulgence or sympathy till they are induced, for their own good, to apply their muse rather to reading what is good than to writing what is bad. For if the bungling of the incompetent so raised the wrath of the gentle Apollo that he could flay Marsyas, I do not see on what the mediocre poets will base their claim to tolerance.

60.

61.

Cf. Ch. xxxvii. of the Supplement.

62.

Leibnitii epistolæ, collectio Kortholti, ep. 154.

63.

Cf. Ch. xxxix. of Supplement.

64.

The following remark may assist those for whom it is not too subtle to understand clearly that the individual is only the phenomenon, not the thing in itself. Every individual is, on the one hand, the subject of knowing, *i.e.*, the complemental condition of the possibility of the whole objective world, and, on the other hand, a particular phenomenon of will, the same will which objectifies itself in everything. But this double nature of our being does not rest upon a self-existing unity, otherwise it would be possible for us to be conscious of ourselves *in ourselves, and independent of the objects of knowledge and will*. Now this is by no means possible, for as soon as we turn into ourselves to make the attempt, and seek for once to know ourselves fully by means of introspective reflection, we are lost in a bottomless void; we find ourselves like the hollow glass globe, from out of which a voice speaks whose cause is not to be found in it, and whereas we desired to comprehend ourselves, we find, with a shudder, nothing but a vanishing spectre.

65.

“Scholastici docuerunt, quod æternitas non sit temporis sine fine aut principio successio; sed *Nunc stans*, *i.e.*, idem nobis *Nunc esse*, quod erat *Nunc Adamo*, *i.e.*, inter *nunc* et *tunc* nullam esse differentiam.” — Hobbes, Leviathan, c. 46.

66.

In Eckermann’s “Conversations of Goethe” (vol. i. p. 161), Goethe says: “Our spirit is a being of a nature quite indestructible, and its activity continues from eternity to eternity. It is like the sun, which seems to set only to our earthly eyes, but which, in reality, never sets, but shines on unceasingly.” Goethe has taken the simile from me; not I from him. Without doubt he used it in this conversation, which was held in 1824, in consequence of a (possibly unconscious) reminiscence of the above passage, for it occurs in the first edition, p. 401, in exactly the same words, and it is also repeated at p. 528 of that edition, as at the close of § 65 of the present work. The first edition was sent to him in December 1818, and in March 1819, when I was at Naples, he sent me his congratulations by letter, through my sister, and enclosed a piece of paper upon which he had noted the places of certain passages which had specially pleased him. Thus he had read my book.

67.

This is expressed in the Veda by saying, that when a man dies his sight becomes one with the sun, his smell with the earth, his taste with water, his hearing with the air, his speech with fire, &c., &c. (Oupnek'hat, vol. i. p. 249 *et seq.*) And also by the fact that, in a special ceremony, the dying man gives over his senses and all his faculties singly to his son, in whom they are now supposed to live on (Oupnek'hat, vol. ii. p. 82 *et seq.*)

68.

71.

Herodot. vii. 46.

72.

Cf. Ch. xlvi. of Supplement.

73.

Cf. Ch. xlv. of the Supplement.

74.

Thus the basis of natural right of property does not require the assumption of two grounds of right beside each other, that based on *detention* and that based on *formation*; but the latter is itself sufficient. Only the name *formation* is not very suitable, for the spending of any labour upon a thing does not need to be a forming or fashioning of it.

75.

The further exposition of the philosophy of law here laid down will be found in my prize-essay, “Ueber das Fundament der Moral,” § 17, pp. 221-230 of 1st ed., pp. 216-226 of 2d ed.

76.

Cf. Ch. xlvii. of Supplement.

77.

Oupnek’hat, vol. i. p. 60 et seq.

78.

That Spanish bishop who, in the last war, poisoned both himself and the French generals at his own table, is an instance of this; and also various incidents in that war. Examples are also to be found in Montaigne, Bk. ii. ch. 12.

79.

Observe, in passing, that what gives every positive system of religion its great strength, the point of contact through which it takes possession of the soul, is entirely its ethical side. Not, however, the ethical side directly as such, but as it appears firmly united and interwoven with the element of mythical dogma which is present in every system of religion, and as intelligible only by means of this. So much is this the case, that although the ethical significance of action cannot be explained in accordance with the principle of sufficient reason, yet since every mythus follows this principle, believers regard the ethical significance of action as quite inseparable, and indeed as absolutely identical, and regard every attack upon the mythus as an attack upon right and virtue. This goes so far that among monotheistic nations atheism or godlessness has become synonymous with the absence of all morality. To the priests such confusions of conceptions are welcome, and only in consequence of them could that horrible monstrosity fanaticism arise and govern, not merely single individuals who happen to be specially perverse and bad, but whole nations, and finally embody itself in the Western world as the Inquisition (to the honour of mankind be it said that this only happened once in their history), which, according to the latest and most authentic accounts, in Madrid alone (in the rest of Spain there were many more such ecclesiastical dens of murderers) in 300 years put 300,000 human beings to a painful death at the stake on theological grounds — a fact of which every zealot ought to be reminded whenever he begins to make himself heard.

80.

The Church would say that these are merely *opera operata*, which do not avail unless grace gives the faith which leads to the new birth. But of this farther on.

81.

The right of man over the life and powers of the brutes rests on the fact that, because with the growing clearness of consciousness suffering increases in like measure; the pain which the brute suffers through death or work is not so great as man would suffer by merely denying himself the flesh, or the powers of the brutes. Therefore man may carry the assertion of his existence to the extent of denying the existence of the brute, and the will to live as a whole endures less suffering in this way than if the opposite course were adopted. This at once determines the extent of the use man may make of the powers of the brutes without wrong; a limit, however, which is often transgressed, especially in the case of beasts of burden and dogs used in the chase; to which the activity of societies for the prevention of cruelty to animals is principally devoted. In my opinion, that right does not extend to vivisection, particularly of the higher animals. On the other hand, the insect does not suffer so much through its death as a man suffers from its sting. The Hindus do not understand this.

82.

As I wander sunk in thought, so strong a sympathy with myself comes over me that I must often weep aloud, which otherwise I am not wont to do.

83.

Cf. Ch. xlvii. of Supplement. It is scarcely necessary to remind the reader that the whole ethical doctrine given in outline in §§ [93]93-[94]94 has been explained fully and in detail in my prize-essay on the foundation of morals.

84.

This thought is expressed by a beautiful simile in the ancient philosophical Sanscrit writing, "Sankhya Karica:" "Yet the soul remains a while invested with body; as the potter's wheel continues whirling after the pot has been fashioned, by force of the impulse previously given to it. When separation of the informed soul from its corporeal frame at length takes place and nature in respect of it ceases, then is absolute and final deliverance accomplished." Colebrooke, "On the Philosophy of

the Hindus: Miscellaneous Essays," vol i. p. 271. Also in the "Sankhya Karica by Horace Wilson," § 67, p. 184.

85.

See, for example, "Oupnek'hat, studio Anquetil du Perron," vol. ii., Nos. 138, 144, 145, 146. "Mythologie des Indous," par Mad. de Polier, vol. ii., ch. 13, 14, 15, 16, 17. "Asiatisches Magazin," by Klaproth: in the first volume, "Ueber die Fo-Religion," also "Baghnat Geeta" or "Gespräche zwischen Krishna und Arjoon;" in the second volume, "Moha-Mudgava." Also, "Institutes of Hindu Law, or the Ordinances of Manu," from the Sanscrit, by Sir William Jones (German by Hüttner, 1797), especially the sixth and twelfth chapters. Finally, many passages in the "Asiatic Researches." (In the last forty years Indian literature has grown so much in Europe, that if I were now to complete this note to the first edition, it would occupy several pages.)

86.

At the procession of Jagganath in June 1840, eleven Hindus threw themselves under the wheels, and were instantly killed. (Letter of an East Indian proprietor in the *Times* of 30th December 1840.)

91.

How truly this is the case may be seen from the fact that all the contradictions and inconceivabilities contained in the Christian dogmatics, consistently systematised by Augustine, which have led to the Pelagian insipidity which is opposed to them, vanish as soon as we abstract from the fundamental Jewish dogma, and recognize that man is not the work of another, but of his own will. Then all is at once clear and correct: then there is no need of freedom in the *operari*, for it lies in the *esse*; and there also lies the sin as original sin. The work of grace is, however, our own. To the rationalistic point of view of the day, on the contrary, many doctrines of the Augustinian dogmatics, founded on the New Testament, appear quite untenable, and indeed revolting; for example, predestination. Accordingly Christianity proper is rejected, and a return is made to crude Judaism. But the miscalculation or the original weakness of Christian dogmatics lies — where it is never sought — precisely in that which is withdrawn from all investigation as established and certain. Take this away and the whole of dogmatics is rational; for this dogma destroys theology as it does all other sciences. If any one studies the Augustinian theology in the books "*De Civitate Dei*" (especially in the Fourteenth Book), he experiences something analogous to the feeling of one who tries to make a body stand whose centre of gravity falls outside it; however he may turn it and place it, it always tumbles over again. So here, in spite of all the efforts and sophisms of Augustine, the guilt and misery of the world always falls back on God, who made everything and everything that is in everything, and also knew how all things would go. That Augustine himself was conscious of the difficulty, and puzzled by it, I have already shown in my prize-essay on the Freedom of the Will (ch. iv. pp. 66-68 of the first and second editions). In the same way, the contradiction between the goodness of God and the misery of the world, and also between the freedom of the will and the foreknowledge of God, is the inexhaustible theme of a controversy which lasted nearly a hundred years between the Cartesians, Malebranche, Leibnitz, Bayle, Clarke, Arnauld, and many others. The only dogma which was regarded as fixed by all parties was the existence and attributes of God, and they all unceasingly move in a circle, because they seek to bring these things into harmony, *i.e.*, to solve a sum that will not come right, but always shows a remainder at some new place whenever we have concealed it elsewhere. But it does not occur to any one to seek for the source of the difficulty in the fundamental assumption, although it palpably obtrudes itself. Bayle alone shows that he saw this.

92.

This is also just the Prajna — Paramita of the Buddhists, the "beyond all knowledge," *i.e.*, the point at which subject and object are no more. (Cf. J. J. Schmidt, "Ueber das Mahajana und Pratschna-Paramita.")

VOLUME II.

Appendix: Criticism of the Kantian Philosophy.

C'est le privilège du vrai génie, et surtout du génie qui ouvre une carrière, de faire impunément de grandes fautes. — *Voltaire.*

It is much easier to point out the faults and errors in the work of a great mind than to give a distinct and full exposition of its value. For the faults are particular and finite, and can therefore be fully comprehended; while, on the contrary, the very stamp which genius impresses upon its works is that their excellence is unfathomable and inexhaustible. Therefore they do not grow old, but become the instructor of many succeeding centuries. The perfected masterpiece of a truly great mind will always produce a deep and powerful effect upon the whole human race, so much so that it is impossible to calculate to what distant centuries and lands its enlightening influence may extend. This is always the case; for however cultivated and rich the age may be in which such a masterpiece appears, genius always rises like a palm-tree above the soil in which it is rooted.

But a deep-reaching and widespread effect of this kind cannot take place suddenly, because of the great difference between the genius and ordinary men. The knowledge which that one man in one lifetime drew directly from life and the world, won and presented to others as won and arranged, cannot yet at once become the possession of mankind; for mankind has not so much power to receive as the genius has power to give. But even after a successful battle with unworthy opponents, who at its very birth contest the life of what is immortal and desire to nip in the bud the salvation of man (like the serpents in the cradle of Hercules), that knowledge must then traverse the circuitous paths of innumerable false constructions and distorted applications, must overcome the attempts to unite it with old errors, and so live in conflict till a new and unprejudiced generation grows up to meet it. Little by little, even in youth, this new generation partially receives the contents of that spring through a thousand indirect channels, gradually assimilates it, and so participates in the benefit which was destined to flow to mankind from that great mind. So slowly does the education of the human race, the weak yet refractory pupil of genius, advance. Thus with Kant's teaching also; its full strength and importance will only be revealed through time, when the spirit of the age, itself gradually transformed and altered in the most important and essential respects by the influence of that teaching, will afford convincing evidence

of the power of that giant mind. I have, however, no intention of presumptuously anticipating the spirit of the age and assuming here the thankless *rôle* of Calchas and Cassandra. Only I must be allowed, in accordance with what has been said, to regard Kant's works as still very new, while many at the present day look upon them as already antiquated, and indeed have laid them aside as done with, or, as they express it, have left them behind; and others, emboldened by this, ignore them altogether, and with brazen face go on philosophising about God and the soul on the assumption of the old realistic dogmatism and its scholastic teaching, which is as if one sought to introduce the doctrines of the alchemists into modern chemistry. For the rest, the works of Kant do not stand in need of my feeble eulogy, but will themselves for ever praise their author, and though perhaps not in the letter, yet in the spirit they will live for ever upon earth.

Certainly, however, if we look back at the first result of his teaching, at the efforts and events in the sphere of philosophy during the period that has elapsed since he wrote, a very depressing saying of Goethe obtains confirmation: "As the water that is displaced by a ship immediately flows in again behind it, so when great minds have driven error aside and made room for themselves, it very quickly closes in behind them again by the law of its nature" (*Wahrheit und Dichtung*, Theil 3, s. 521). Yet this period has been only an episode, which is to be reckoned as part of the lot referred to above that befalls all new and great knowledge; an episode which is now unmistakably near its end, for the bubble so long blown out yet bursts at last. Men generally are beginning to be conscious that true and serious philosophy still stands where Kant left it. At any rate, I cannot see that between Kant and myself anything has been done in philosophy; therefore I regard myself as his immediate successor.

What I have in view in this Appendix to my work is really only a defence of the doctrine I have set forth in it, inasmuch as in many points that doctrine does not agree with the Kantian philosophy, but indeed contradicts it. A discussion of this philosophy is, however, necessary, for it is clear that my train of thought, different as its content is from that of Kant, is yet throughout under its influence, necessarily presupposes it, starts from it; and I confess that, next to the impression of the world of perception, I owe what is best in my own system to the impression made upon me by the works of Kant, by the sacred writings of the Hindus, and by Plato. But I can only justify the contradictions of Kant which are nevertheless present in my

work by accusing him of error in these points, and exposing mistakes which he committed. Therefore in this Appendix I must proceed against Kant in a thoroughly polemical manner, and indeed seriously and with every effort; for it is only thus that his doctrine can be freed from the error that clings to it, and its truth shine out the more clearly and stand the more firmly. It must not, therefore, be expected that the sincere reverence for Kant which I certainly feel shall extend to his weaknesses and errors also, and that I shall consequently refrain from exposing these except with the most careful indulgence, whereby my language would necessarily become weak and insipid through circumlocution. Towards a living writer such indulgence is needed, for human frailty cannot endure even the most just refutation of an error, unless tempered by soothing and flattery, and hardly even then; and a teacher of the age and benefactor of mankind deserves at least that the human weakness he also has should be indulged, so that he may not be caused pain. But he who is dead has thrown off this weakness; his merit stands firm; time will purify it more and more from all exaggeration and detraction. His mistakes must be separated from it, rendered harmless, and then given over to oblivion. Therefore in the polemic against Kant I am about to begin, I have only his mistakes and weak points in view. I oppose them with hostility, and wage a relentless war of extermination against them, always mindful not to conceal them indulgently, but rather to place them in the clearest light, in order to extirpate them the more surely. For the reasons given above, I am not conscious either of injustice or ingratitude towards Kant in doing this. However, in order that, in the eyes of others also, I may remove every appearance of malice, I wish first to bring out clearly my sincere reverence for Kant and gratitude to him, by expressing shortly what in my eyes appears to be his chief merit; and I shall do this from a standpoint so general that I shall not require to touch upon the points in which I must afterwards controvert him.

Kant's greatest merit is the distinction of the phenomenon from the thing in itself, based upon the proof that between things and us there still always stands the *intellect*, so that they cannot be known as they may be in themselves. He was led into this path through Locke (see *Prolegomena zu jeder Metaph.*, § 13, Anm. 2). The latter had shown that the secondary qualities of things, such as sound, smell, colour, hardness, softness, smoothness, and the like, as founded on the affections of the senses, do not

belong to the objective body, to the thing in itself. To this he attributed only the primary qualities, *i.e.*, such as only presuppose space and impenetrability; thus extension, figure, solidity, number, mobility. But this easily discovered Lockeian distinction was, as it were, only a youthful introduction to the distinction of Kant. The latter, starting from an incomparably higher standpoint, explains all that Locke had accepted as *primary qualities*, *i.e.*, qualities of the thing in itself, as also belonging only to its phenomenal appearance in our faculty of apprehension, and this just because the conditions of this faculty, space, time, and causality, are known by us *a priori*. Thus Locke had abstracted from the thing in itself the share which the organs of sense have in its phenomenal appearance; Kant, however, further abstracted the share of the brain-functions (though not under that name). Thus the distinction between the phenomenon and the thing in itself now received an infinitely greater significance, and a very much deeper meaning. For this end he was obliged to take in hand the important separation of our *a priori* from our *a posteriori* knowledge, which before him had never been carried out with adequate strictness and completeness, nor with distinct consciousness. Accordingly this now became the principal subject of his profound investigations. Now here we would at once remark that Kant's philosophy has a threefold relation to that of his predecessors. First, as we have just seen, to the philosophy of Locke, confirming and extending it; secondly, to that of Hume, correcting and making use of it, a relation which is most distinctly expressed in the "*Prolegomena*" (that most beautiful and comprehensible of all Kant's important writings, which is far too little read, for it facilitates immensely the study of his philosophy); thirdly, a decidedly polemical and destructive relation to the Leibnitz-Wolfian philosophy. All three systems ought to be known before one proceeds to the study of the Kantian philosophy. If now, according to the above, the distinction of the phenomenon from the thing in itself, thus the doctrine of the complete diversity of the ideal and the real, is the fundamental characteristic of the Kantian philosophy, then the assertion of the absolute identity of these two which appeared soon afterwards is a sad proof of the saying of Goethe quoted above; all the more so as it rested upon nothing but the empty boast of intellectual intuition, and accordingly was only a return to the crudeness of the vulgar opinion, masked under bombast and nonsense, and the imposing impression of an air of importance. It became the fitting starting-point for the still grosser nonsense

of the clumsy and stupid Hegel. Now as Kant's separation of the phenomenon from the thing in itself, arrived at in the manner explained above, far surpassed all that preceded it in the depth and thoughtfulness of its conception, it was also exceedingly important in its results. For in it he propounded, quite originally, in a perfectly new way, found from a new side and on a new path, the same truth which Plato never wearies of repeating, and in his language generally expresses thus: This world which appears to the senses has no true being, but only a ceaseless becoming; it is, and it is not, and its comprehension is not so much knowledge as illusion. This is also what he expresses mythically at the beginning of the seventh book of the Republic, the most important passage in all his writings, which has already been referred to in the third book of the present work. He says: Men, firmly chained in a dark cave, see neither the true original light nor real things, but only the meagre light of the fire in the cave and the shadows of real things which pass by the fire behind their backs; yet they think the shadows are the reality, and the determining of the succession of these shadows is true wisdom. The same truth, again quite differently presented, is also a leading doctrine of the Vedas and Puranas, the doctrine of Mâyâ, by which really nothing else is understood than what Kant calls the phenomenon in opposition to the thing in itself; for the work of Mâyâ is said to be just this visible world in which we are, a summoned enchantment, an inconstant appearance without true being, like an optical illusion or a dream, a veil which surrounds human consciousness, something of which it is equally false and true to say that it is and that it is not. But Kant not only expressed the same doctrine in a completely new and original way, but raised it to the position of proved and indisputable truth by means of the calmest and most temperate exposition; while both Plato and the Indian philosophers had founded their assertions merely upon a general perception of the world, had advanced them as the direct utterance of their consciousness, and presented them rather mythically and poetically than philosophically and distinctly. In this respect they stand to Kant in the same relation as the Pythagoreans Hicetas, Philolaus, and Aristarchus, who already asserted the movement of the earth round the fixed sun, stand to Copernicus. Such distinct knowledge and calm, thoughtful exposition of this dream-like nature of the whole world is really the basis of the whole Kantian philosophy; it is its soul and its greatest merit. He accomplished this by taking to pieces the whole machinery of our intellect by means of

which the phantasmagoria of the objective world is brought about, and presenting it in detail with marvellous insight and ability. All earlier Western philosophy, appearing in comparison with the Kantian unspeakably clumsy, had failed to recognise that truth, and had therefore always spoken just as if in a dream. Kant first awakened it suddenly out of this dream; therefore the last sleepers (Mendelssohn) called him the "all-destroyer." He showed that the laws which reign with inviolable necessity in existence, *i.e.*, in experience generally, are not to be applied to deduce and explain *existence itself* that thus the validity of these laws is only relative, *i.e.*, only arises after existence; the world of experience in general is already established and present; that consequently these laws cannot be our guide when we come to the explanation of the existence of the world and of ourselves. All earlier Western philosophers had imagined that these laws, according to which the phenomena are combined, and all of which — time and space, as well as causality and inference — I comprehend under the expression "the principle of sufficient reason," were absolute laws conditioned by nothing, *æternæ veritates*; that the world itself existed only in consequence of and in conformity with them; and therefore that under their guidance the whole riddle of the world must be capable of solution. The assumptions made for this purpose, which Kant criticises under the name of the Ideas of the reason, only served to raise the mere phenomenon, the work of Mâyâ, the shadow world of Plato, to the one highest reality, to put it in the place of the inmost and true being of things, and thereby to make the real knowledge of this impossible; that is, in a word, to send the dreamers still more soundly to sleep. Kant exhibited these laws, and therefore the whole world, as conditioned by the form of knowledge belonging to the subject; from which it followed, that however far one carried investigation and reasoning under the guidance of these laws, yet in the principal matter, *i.e.*, in knowledge of the nature of the world in itself and outside the idea, no step in advance was made, but one only moved like a squirrel in its wheel. Thus, all the dogmatists may be compared to persons who supposed that if they only went straight on long enough they would come to the end of the world; but Kant then circumnavigated the world and showed that, because it is round, one cannot get out of it by horizontal movement, but that yet by perpendicular movement this is perhaps not impossible. We may also say that Kant's doctrine affords the insight that we must seek the end and beginning of the world, not without, but within us.

All this, however, rests on the fundamental distinction between dogmatic and *critical* or *transcendental philosophy*. Whoever wishes to make this quite clear to himself, and realise it by means of an example, may do so very briefly by reading, as a specimen of dogmatic philosophy, an essay of Leibnitz entitled "*De Rerum Originatione Radicali*," and printed for the first time in the edition of the philosophical works of Leibnitz by Erdmann (vol. i. p. 147). Here the origin and excellence of the world is demonstrated *a priori*, so thoroughly in the manner of realistic-dogmatism, on the ground of the *veritates æternæ* and with the assistance of the ontological and cosmological proofs. It is indeed once admitted, by the way, that experience shows the exact opposite of the excellence of the world here demonstrated; but experience is therefore given to understand that it knows nothing of the matter, and ought to hold its tongue when philosophy has spoken a priori. Now, with Kant, the *critical philosophy* appeared as the opponent of this whole method. It takes for its problem just these *veritates æternæ*, which serve as the foundation of every such dogmatic structure, investigates their origin, and finds it in the human mind, where they spring from the peculiar forms which belong to it, and which it carries in itself for the purpose of comprehending an objective world. Thus, here, in the brain, is the quarry which supplies the material for that proud dogmatic edifice. But because the critical philosophy, in order to attain to this result, was obliged to go beyond the *veritates æternæ* upon which all the preceding dogmatism was founded, and make these truths themselves the objects of investigation, it became *transcendental* philosophy. From this, then, it also follows that the objective world, as we know it, does not belong to the true being of the thing in itself, but is merely its phenomenal appearance conditioned by those very forms which lie *a priori* in the intellect (*i.e.*, the brain), therefore it cannot contain anything but phenomena.

Kant, indeed, did not attain to the knowledge that the phenomenon is the world as idea, and the thing in itself is the will. But he showed that the phenomenal world is conditioned just as much through the subject as through the object, and because he isolated the most universal forms of its phenomenal appearance, *i.e.*, of the idea, he proved that we may know these forms and consider them in their whole constitution, not only by starting from the object, but also just as well by starting from the subject, because

they are really the limits between object and subject which are common to them both; and he concluded that by following these limits we never penetrate to the inner nature either of the object or of the subject, consequently never know the true nature of the world, the thing in itself.

He did not deduce the thing in itself in the right way, as I shall show presently, but by means of an inconsistency, and he had to pay the penalty of this in frequent and irresistible attacks upon this important part of his teaching. He did not recognise the thing in itself directly in the will; but he made a great initial step towards this knowledge in that he explained the undeniable moral significance of human action as quite different from and not dependent upon the laws of the phenomenon, nor even explicable in accordance with them, but as something which touches the thing in itself directly: this is the second important point of view for estimating his services.

We may regard as the third the complete overthrow of the Scholastic philosophy, a name by which I wish here to denote generally the whole period beginning with Augustine, the Church Father, and ending just before Kant. For the chief characteristic of Scholasticism is, indeed, that which is very correctly stated by Tennemann, the guardianship of the prevailing national religion over philosophy, which had really nothing left for it to do but to prove and embellish the cardinal dogmas prescribed to it by religion. The Schoolmen proper, down to Suarez, confess this openly; the succeeding philosophers do it more unconsciously, or at least unavowedly. It is held that Scholastic philosophy only extends to about a hundred years before Descartes, and that then with him there begins an entirely new epoch of free investigation independent of all positive theological doctrine. Such investigation, however, is in fact not to be attributed to Descartes and his successors,[1] but only an appearance of it, and in any case an effort after it. Descartes was a man of supreme ability, and if we take account of the age he lived in, he accomplished a great deal. But if we set aside this consideration and measure him with reference to the freeing of thought from all fetters and the commencement of a new period of untrammelled original investigation with which he is credited, we are obliged to find that with his doubt still wanting in true seriousness, and therefore surrendering so quickly and so entirely, he has, indeed, the appearance of wishing to throw off at once all the early implanted opinions belonging to his age and nation, but does so only apparently and for a moment, to assume them again

immediately and hold them all the more firmly; and so is it with all his successors down to Kant. Goethe's lines are, therefore, very applicable to a free independent thinker of this kind:

"Saving Thy gracious presence, he to me
A long-legged grasshopper appears to be,
That springing flies, and flying springs,
And in the grass the same old ditty sings."[2]

Kant had reasons for assuming the air of also intending nothing more. But the pretended spring, which was permitted because it was known that it leads back to the grass, this time became a flight, and now those who remain below can only look after him, and can never catch him again.

Kant, then, ventured to show by his teaching that all those dogmas which had been so often professedly proved were incapable of proof. Speculative theology, and the rational psychology connected with it, received from him their deathblow. Since then they have vanished from German philosophy, and one must not allow oneself to be misled by the fact that here and there the word is retained after the thing has been given up, or some wretched professor of philosophy has the fear of his master in view, and lets truth take care of itself. Only he who has observed the pernicious influence of these conceptions upon natural science, and upon philosophy in all, even the best writers of the seventeenth and eighteenth centuries, can estimate the extent of this service of Kant's. The change of tone and of metaphysical background which has appeared in German writing upon natural science since Kant is remarkable; before him it was in the same position as it still occupies in England. This merit of Kant's is connected with the fact that the unreflecting pursuit of the laws of the phenomenon, the elevation of these to the position of eternal truths, and thus the raising of the fleeting appearance to the position of the real being of the world, in short, *realism* undisturbed in its illusion by any reflection, had reigned throughout all preceding philosophy, ancient, mediæval, and modern. Berkeley, who, like Malebranche before him, recognised its one-sidedness, and indeed falseness, was unable to overthrow it, for his attack was confined to *one* point. Thus it was reserved for Kant to enable the idealistic point of view to obtain the ascendancy in Europe, at least in philosophy; the point of view which throughout all non-Mohammedan Asia, and indeed essentially, is that of religion. Before Kant, then, we were in time; now time is in us, and so on.

Ethics also were treated by that realistic philosophy according to the laws of the phenomenon, which it regarded as absolute and valid also for the thing in itself. They were therefore based now upon a doctrine of happiness, now upon the will of the Creator, and finally upon the conception of perfection; a conception which, taken by itself, is entirely empty and void of content, for it denotes a mere relation that only receives significance from the things to which it is applied. "To be perfect" means nothing more than "to correspond to some conception which is presupposed and given," a conception which must therefore be previously framed, and without which the perfection is an unknown quantity, and consequently has no meaning when expressed alone. If, however, it is intended tacitly to presuppose the conception "humanity," and accordingly to make it the principle of morality to strive after human perfection, this is only saying: "Men ought to be as they ought to be," — and we are just as wise as before. In fact "perfect" is very nearly a mere synonym of "complete," for it signifies that in one given case or individual, all the predicates which lie in the conception of its species appear, thus are actually present. Therefore the conception "perfection," if used absolutely and in the abstract, is a word void of significance, and this is also the case with the talk about the "most perfect being," and other similar expressions. All this is a mere jingle of words. Nevertheless last century this conception of perfection and imperfection had become current coin; indeed it was the hinge upon which almost all speculation upon ethics, and even theology, turned. It was in every one's mouth, so that at last it became a simple nuisance. We see even the best writers of the time, for example Lessing, entangled in the most deplorable manner in perfections and imperfections, and struggling with them. At the same time, every thinking man must at least dimly have felt that this conception is void of all positive content, because, like an algebraical symbol, it denotes a mere relation *in abstracto*. Kant, as we have already said, entirely separated the undeniably great ethical significance of actions from the phenomenon and its laws, and showed that the former directly concerned the thing in itself, the inner nature of the world, while the latter, *i.e.*, time, space, and all that fills them, and disposes itself in them according to the law of causality, is to be regarded as a changing and unsubstantial dream.

The little I have said, which by no means exhausts the subject, may suffice as evidence of my recognition of the great merits of Kant, — a

recognition expressed here both for my own satisfaction, and because justice demands that those merits should be recalled to the memory of every one who desires to follow me in the unsparing exposure of his errors to which I now proceed.

It may be inferred, upon purely historical grounds, that Kant's great achievements must have been accompanied by great errors. For although he effected the greatest revolution in philosophy and made an end of Scholasticism, which, understood in the wider sense we have indicated, had lasted for fourteen centuries, in order to begin what was really the third entirely new epoch in philosophy which the world has seen, yet the direct result of his appearance was only negative, not positive. For since he did not set up a completely new system, to which his disciples could only have adhered for a period, all indeed observed that something very great had happened, but yet no one rightly knew what. They certainly saw that all previous philosophy had been fruitless dreaming, from which the new age had now awakened, but what they ought to hold to now they did not know. A great void was felt; a great need had arisen; the universal attention even of the general public was aroused. Induced by this, but not urged by inward inclination and sense of power (which find utterance even at unfavourable times, as in the case of Spinoza), men without any exceptional talent made various weak, absurd, and indeed sometimes insane, attempts, to which, however, the now interested public gave its attention, and with great patience, such as is only found in Germany, long lent its ear.

The same thing must once have happened in Nature, when a great revolution had altered the whole surface of the earth, land and sea had changed places, and the scene was cleared for a new creation. It was then a long time before Nature could produce a new series of lasting forms all in harmony with themselves and with each other. Strange and monstrous organisations appeared which did not harmonise either with themselves or with each other, and therefore could not endure long, but whose still existing remains have brought down to us the tokens of that wavering and tentative procedure of Nature forming itself anew.

Since, now, in philosophy, a crisis precisely similar to this, and an age of fearful abortions, was, as we all know, introduced by Kant, it may be concluded that the services he rendered were not complete, but must have

been negative and one-sided, and burdened with great defects. These defects we now desire to search out.

First of all we shall present to ourselves clearly and examine the fundamental thought in which the aim of the whole "Critique of Pure Reason" lies. Kant placed himself at the standpoint of his predecessors, the dogmatic philosophers, and accordingly he started with them from the following assumptions: — (1.) Metaphysics is the science of that which lies beyond the possibility of all experience. (2.) Such a science can never be attained by applying principles which must first themselves be drawn from experience (*Prolegomena*, § 1); but only what we know *before*, and thus *independently of* all experience, can reach further than possible experience. (3.) In our reason certain principles of this kind are actually to be found: they are comprehended under the name of Knowledge of pure reason. So far Kant goes with his predecessors, but here he separates from them. They say: "These principles, or this knowledge of pure reason, are expressions of the absolute possibility of things, *æternæ veritates*, sources of ontology; they stand above the system of the world, as fate stood above the gods of the ancients." Kant says, they are mere forms of our intellect, laws, not of the existence of things, but of our idea of them; they are therefore valid merely for our apprehension of things, and hence they cannot extend beyond the possibility of experience, which, according to assumption 1, is what was aimed at; for the *a priori* nature of these forms of knowledge, since it can only rest on their subjective origin, is just what cuts us off for ever from the knowledge of the nature of things in themselves, and confines us to a world of mere phenomena, so that we cannot know things as they may be in themselves, even *a posteriori*, not to speak of *a priori*. Accordingly metaphysics is impossible, and criticism of pure reason takes its place. As opposed to the old dogmatism, Kant is here completely victorious; therefore all dogmatic attempts which have since appeared have been obliged to pursue an entirely different path from the earlier systems; and I shall now go on to the justification of my own system, according to the expressed intention of this criticism. A more careful examination, then, of the reasoning given above will oblige one to confess that its first fundamental assumption is a *petitio principii*. It lies in the proposition (stated with particular clearness in the *Prolegomena*, § 1): "The source of metaphysics must throughout be non-empirical; its fundamental principles

and conceptions must never be taken from either inner or outer experience." Yet absolutely nothing is advanced in proof of this cardinal assertion except the etymological argument from the word metaphysic. In truth, however, the matter stands thus: The world and our own existence presents itself to us necessarily as a riddle. It is now assumed, without more ado, that the solution of this riddle cannot be arrived at from a thorough understanding of the world itself, but must be sought in something entirely different from the world (for that is the meaning of "beyond the possibility of all experience"); and that everything must be excluded from that solution of which we can in any way have *immediate* knowledge (for that is the meaning of possible experience, both inner and outer); the solution must rather be sought only in that at which we can arrive merely indirectly, that is, by means of inferences from universal principles *a priori*. After the principal source of all knowledge has in this way been excluded, and the direct way to truth has been closed, we must not wonder that the dogmatic systems failed, and that Kant was able to show the necessity of this failure; for metaphysics and knowledge *a priori* had been assumed beforehand to be identical. But for this it was first necessary to prove that the material for the solution of the riddle absolutely cannot be contained in the world itself, but must be sought for only outside the world in something we can only attain to under the guidance of those forms of which we are conscious *a priori*. But so long as this is not proved, we have no grounds for shutting ourselves off, in the case of the most important and most difficult of all questions, from the richest of all sources of knowledge, inner and outer experience, in order to work only with empty forms. I therefore say that the solution of the riddle of the world must proceed from the understanding of the world itself; that thus the task of metaphysics is not to pass beyond the experience in which the world exists, but to understand it thoroughly, because outer and inner experience is at any rate the principal source of all knowledge; that therefore the solution of the riddle of the world is only possible through the proper connection of outer with inner experience, effected at the right point, and the combination thereby produced of these two very different sources of knowledge. Yet this solution is only possible within certain limits which are inseparable from our finite nature, so that we attain to a right understanding of the world itself without reaching a final explanation of its existence abolishing all further problems. Therefore *est quadam prodire tenus*, and my path lies midway between the omniscience of the earlier dogmatists and

the despair of the Kantian Critique. The important truths, however, which Kant discovered, and through which the earlier metaphysical systems were overthrown, have supplied my system with data and materials. Compare what I have said concerning my method in chap. xvii. of the Supplements. So much for the fundamental thought of Kant; we shall now consider his working out of it and its details.

Kant's style bears throughout the stamp of a pre-eminent mind, genuine strong individuality, and quite exceptional power of thought. Its characteristic quality may perhaps be aptly described as a *brilliant dryness*, by virtue of which he was able to grasp firmly and select the conceptions with great certainty, and then to turn them about with the greatest freedom, to the astonishment of the reader. I find the same brilliant dryness in the style of Aristotle, though it is much simpler. Nevertheless Kant's language is often indistinct, indefinite, inadequate, and sometimes obscure. Its obscurity, certainly, is partly excusable on account of the difficulty of the subject and the depth of the thought; but he who is himself clear to the bottom, and knows with perfect distinctness what he thinks and wishes, will never write indistinctly, will never set up wavering and indefinite conceptions, compose most difficult and complicated expressions from foreign languages to denote them, and use these expressions constantly afterwards, as Kant took words and formulas from earlier philosophy, especially Scholasticism, which he combined with each other to suit his purposes; as, for example, "transcendental synthetic unity of apperception," and in general "unity of synthesis" (*Einheit der Synthesis*), always used where "union" (*Vereinigung*) would be quite sufficient by itself. Moreover, a man who is himself quite clear will not be always explaining anew what has once been explained, as Kant does, for example, in the case of the understanding, the categories, experience, and other leading conceptions. In general, such a man will not incessantly repeat himself, and yet in every new exposition of the thought already expressed a hundred times leave it in just the same obscure condition, but he will express his meaning once distinctly, thoroughly, and exhaustively, and then let it alone. "*Quo enim melius rem aliquam concipimus eo magis determinati sumus ad eam unico modo exprimendam*," says Descartes in his fifth letter. But the most injurious result of Kant's occasionally obscure language is, that it acted as *exemplar vitiis imitabile*; indeed, it was misconstrued as a pernicious

authorisation. The public was compelled to see that what is obscure is not always without significance; consequently, what was without significance took refuge behind obscure language. Fichte was the first to seize this new privilege and use it vigorously; Schelling at least equalled him; and a host of hungry scribblers, without talent and without honesty, soon outbade them both. But the height of audacity, in serving up pure nonsense, in stringing together senseless and extravagant mazes of words, such as had previously only been heard in madhouses, was finally reached in Hegel, and became the instrument of the most barefaced general mystification that has ever taken place, with a result which will appear fabulous to posterity, and will remain as a monument of German stupidity. In vain, meanwhile, Jean Paul wrote his beautiful paragraph, "Higher criticism of philosophical madness in the professorial chair, and poetical madness in the theatre" (*Æsthetische Nachschule*); for in vain Goethe had already said —

"They prate and teach, and no one interferes;
All from the fellowship of fools are shrinking;
Man usually believes, if only words he hears,
That also with them goes material for thinking."[3]

But let us return to Kant. We are compelled to admit that he entirely lacks grand, classical simplicity, *naïveté*, *ingénuité*, *candeur*. His philosophy has no analogy with Grecian architecture, which presents large simple proportions revealing themselves at once to the glance; on the contrary, it reminds us strongly of the Gothic style of building. For a purely individual characteristic of Kant's mind is a remarkable love of *symmetry*, which delights in a varied multiplicity, so that it may reduce it to order, and repeat this order in subordinate orders, and so on indefinitely, just as happens in Gothic churches. Indeed, he sometimes carries this to the extent of trifling, and from love of this tendency he goes so far as to do open violence to truth, and to deal with it as Nature was dealt with by the old-fashioned gardeners, whose work we see in symmetrical alleys, squares, and triangles, trees shaped like pyramids and spheres, and hedges winding in regular curves. I will support this with facts.

After he has treated space and time isolated from everything else, and has then dismissed this whole world of perception which fills space and time, and in which we live and are, with the meaningless words "the empirical content of perception is given us," he immediately arrives with one spring at *the logical basis of his whole philosophy, the table of*

judgments. From this table he deduces an exact dozen of categories, symmetrically arranged under four heads, which afterwards become the fearful procrustean bed into which he violently forces all things in the world and all that goes on in man, shrinking from no violence and disdaining no sophistry if only he is able to repeat everywhere the symmetry of that table. The first that is symmetrically deduced from it is the pure physiological table of the general principles of natural science — the axioms of intuition, anticipations of perception, analogies of experience, and postulates of empirical thought in general. Of these fundamental principles, the first two are simple; but each of the last two sends out symmetrically three shoots. The mere categories were what he calls *conceptions*; but these principles of natural science are *judgments*. In accordance with his highest guide to all wisdom, symmetry, the series must now prove itself fruitful in the syllogisms, and this, indeed, is done symmetrically and regularly. For, as by the application of the categories to sensibility, experience with all its *a priori* principles arose for the understanding, so by the application of *syllogisms* to the categories, a task performed by the *reason* in accordance with its pretended principle of seeking the unconditioned, the *Ideas* of the reason arise. Now this takes place in the following manner: The three categories of relation supply to syllogistic reasoning the three only possible kinds of major premisses, and syllogistic reasoning accordingly falls into three kinds, each of which is to be regarded as an egg out of which the reason hatches an Idea; out of the categorical syllogism the Idea of the *soul*, out of the hypothetical the Idea of the *world*, and out of the disjunctive the Idea of *God*. In the second of these, the Idea of the world, the symmetry of the table of the categories now repeats itself again, for its four heads produce four theses, each of which has its antithesis as a symmetrical pendant.

We pay the tribute of our admiration to the really exceedingly acute combination which produced this elegant structure, but we shall none the less proceed to a thorough examination of its foundation and its parts. But the following remarks must come first.

It is astonishing how Kant, without further reflection, pursues his way, following his symmetry, ordering everything in accordance with it, without ever taking one of the subjects so handled into consideration on its own account. I will explain myself more fully. After he has considered intuitive

knowledge in a mathematical reference only, he neglects altogether the rest of knowledge of perception in which the world lies before us, and confines himself entirely to abstract thinking, although this receives the whole of its significance and value from the world of perception alone, which is infinitely more significant, generally present, and rich in content than the abstract part of our knowledge. Indeed, and this is an important point, he has nowhere clearly distinguished perception from abstract knowledge, and just on this account, as we shall afterwards see, he becomes involved in irresolvable contradictions with himself. After he has disposed of the whole sensible world with the meaningless "it is given," he makes, as we have said, the logical table of judgments the foundation-stone of his building. But here again he does not reflect for a moment upon that which really lies before him. These forms of judgment are indeed *words* and *combinations of words*; yet it ought first to have been asked what these directly denote: it would have been found that they denote *conceptions*. The next question would then have been as to the nature of *conceptions*. It would have appeared from the answer what relation these have to the ideas of perception in which the world exists; for perception and reflection would have been distinguished. It would now have become necessary to examine, not merely how pure and merely formal intuition or perception *a priori*, but also how its content, the empirical perception, comes into consciousness. But then it would have become apparent what part the *understanding* has in this, and thus also in general what the *understanding* is, and, on the other hand, what the *reason* properly is, the critique of which is being written. It is most remarkable that he does not once properly and adequately define the latter, but merely gives incidentally, and as the context in each case demands, incomplete and inaccurate explanations of it, in direct contradiction to the rule of Descartes given above.[4] For example, at p. 11; V. 24, of the "Critique of Pure Reason," it is the faculty of principles *a priori*; but at p. 299; V. 356, it is said that reason is the faculty of *principles*, and it is opposed to the understanding, which is the faculty of *rules*! One would now think that there must be a very wide difference between principles and rules, since it entitles us to assume a special faculty of knowledge for each of them. But this great distinction is made to lie merely in this, that what is known *a priori* through pure perception or through the forms of the understanding is a rule, and only what results from mere conceptions is a principle. We shall return to this arbitrary and inadmissible distinction later,

when we come to the Dialectic. On p. 330; V. 386, reason is the faculty of inference; mere judging (p. 69; V. 94) he often explains as the work of the understanding. Now, this really amounts to saying: Judging is the work of the understanding so long as the ground of the judgment is empirical, transcendental, or metalogical (Essay on the Principle of Sufficient Reason, § 31, 32, 33); but if it is logical, as is the case with the syllogism, then we are here concerned with a quite special and much more important faculty of knowledge — the reason. Nay, what is more, on p. 303; V. 360, it is explained that what follows directly from a proposition is still a matter of the understanding, and that only those conclusions which are arrived at by the use of a mediating conception are the work of the reason, and the example given is this: From the proposition, "All men are mortal," the inference, "Some mortals are men," may be drawn by the mere understanding. On the other hand, to draw the conclusion, "All the learned are mortal," demands an entirely different and far more important faculty — the reason. How was it possible for a great thinker to write the like of this! On p. 553; V. 581, reason is all at once the constant condition of all voluntary action. On p. 614; V. 642, it consists in the fact that we can give an account of our assertions; on pp. 643, 644; V. 671, 672, in the circumstance that it brings unity into the conceptions of the understanding by means of Ideas, as the understanding brings unity into the multiplicity of objects by means of conceptions. On p. 646; V. 674, it is nothing else than the faculty which deduces the particular from the general.

The understanding also is constantly being explained anew. In seven passages of the "Critique of Pure Reason" it is explained in the following terms. On p. 51; V. 75, it is the faculty which of itself produces ideas of perception. On p. 69; V. 94, it is the faculty of judging, *i.e.*, of thinking, *i.e.*, of knowing through conceptions. On p. 137 of the fifth edition, it is the faculty of knowledge generally. On p. 132; V. 171, it is the faculty of rules. On p. 158; V. 197, however, it is said: "It is not only the faculty of rules, but the source of principles (*Grundsätze*) according to which everything comes under rules;" and yet above it was opposed to the reason because the latter alone was the faculty of principles (*Principien*). On p. 160; V. 199, the understanding is the faculty of conceptions; but on p. 302; V. 359, it is the faculty of the unity of phenomena by means of rules.

Against such really confused and groundless language on the subject (even though it comes from Kant) I shall have no need to defend the

explanation which I have given of these two faculties of knowledge — an explanation which is fixed, clearly defined, definite, simple, and in full agreement with the language of all nations and all ages. I have only quoted this language as a proof of my charge that Kant follows his symmetrical, logical system without sufficiently reflecting upon the subject he is thus handling.

Now, as I have said above, if Kant had seriously examined how far two such different faculties of knowledge, one of which is the specific difference of man, may be known, and what, in accordance with the language of all nations and all philosophers, reason and understanding are, he would never, without further authority than the *intellectus theoreticus* and *practicus* of the Schoolmen, which is used in an entirely different sense, have divided the reason into theoretical and practical, and made the latter the source of virtuous conduct. In the same way, before Kant separated so carefully conceptions of the understanding (by which he sometimes means his categories, sometimes all general conceptions) and conceptions of the reason (his so-called Ideas), and made them both the material of his philosophy, which for the most part deals only with the validity, application, and origin of all these conceptions; — first, I say, he ought to have really examined what in general a *conception* is. But this very necessary investigation has unfortunately been also neglected, and has contributed much to the irremediable confusion of intuitive and abstract knowledge which I shall soon refer to. The same want of adequate reflection with which he passed over the questions: what is perception? what is reflection? what is conception? what is reason? what is understanding? allowed him to pass over the following investigations, which were just as inevitably necessary: what is it that I call the *object*, which I distinguish from the *idea*? what is existence? what is object? what is subject? what is truth, illusion, error? But he follows his logical schema and his symmetry without reflecting or looking about him. The table of judgments ought to, and must, be the key to all wisdom.

I have given it above as the chief merit of Kant that he distinguished the phenomenon from the thing in itself, explained the whole visible world as phenomenon, and therefore denied all validity to its laws beyond the phenomenon. It is certainly remarkable that he did not deduce this merely relative existence of the phenomenon from the simple undeniable truth

which lay so near him, "*No object without a subject*," in order thus at the very root to show that the object, because it always exists merely in relation to a subject, is dependent upon it, conditioned by it, and therefore conditioned as mere phenomenon, which does not exist in itself nor unconditioned. Berkeley, to whose merits Kant did not do justice, had already made this important principle the foundation-stone of his philosophy, and thereby established an immortal reputation. Yet he himself did not draw the proper conclusions from this principle, and so he was both misunderstood and insufficiently attended to. In my first edition I explained Kant's avoidance of this Berkeleian principle as arising from an evident shrinking from decided idealism; while, on the other hand, I found idealism distinctly expressed in many passages of the "Critique of Pure Reason," and accordingly I charged Kant with contradicting himself. And this charge was well founded, if, as was then my case, one only knew the "Critique of Pure Reason" in the second or any of the five subsequent editions printed from it. But when later I read Kant's great work in the first edition, which is already so rare, I saw, to my great pleasure, all these contradictions disappear, and found that although Kant does not use the formula, "No object without a subject," he yet explains, with just as much decision as Berkeley and I do, the outer world lying before us in space and time as the mere idea of the subject that knows it. Therefore, for example, he says there without reserve (p. 383): "If I take away the thinking subject, the whole material world must disappear, for it is nothing but a phenomenon in the sensibility of our subject, and a class of its ideas." But the whole passage from p. 348-392, in which Kant expounded his pronounced idealism with peculiar beauty and clearness, was suppressed by him in the second edition, and instead of it a number of remarks controverting it were introduced. In this way then the text of the "Critique of Pure Reason," as it has circulated from the year 1787 to the year 1838, was disfigured and spoilt, and it became a self-contradictory book, the sense of which could not therefore be thoroughly clear and comprehensible to any one. The particulars about this, and also my conjectures as to the reasons and the weaknesses which may have influenced Kant so to disfigure his immortal work, I have given in a letter to Professor Rosenkranz, and he has quoted the principal passage of it in his preface to the second volume of the edition of Kant's collected works edited by him, to which I therefore refer. In consequence of my representations, Professor Rosenkranz was induced in the year 1838 to restore the "Critique

of Pure Reason" to its original form, for in the second volume referred to he had it printed according to the *first* edition of 1781, by which he has rendered an inestimable service to philosophy; indeed, he has perhaps saved from destruction the most important work of German literature; and this should always be remembered to his credit. But let no one imagine that he knows the "Critique of Pure Reason" and has a distinct conception of Kant's teaching if he has only read the second or one of the later editions. That is altogether impossible, for he has only read a mutilated, spoilt, and to a certain extent ungenuine text. It is my duty to say this here decidedly and for every one's warning.

Yet the way in which Kant introduces the *thing in itself* stands in undeniable contradiction with the distinctly idealistic point of view so clearly expressed in the first edition of the "Critique of Pure Reason," and without doubt this is the chief reason why, in the second edition, he suppressed the principal idealistic passage we have referred to, and directly declared himself opposed to the Berkeleian idealism, though by doing so he only introduced inconsistencies into his work, without being able to remedy its principal defect. This defect, as is known, is the introduction of the *thing in itself* in the way chosen by him, the inadmissibleness of which was exposed at length by G. E. Schulze in "*Ænesidemus*," and was soon recognised as the untenable point of his system. The matter may be made clear in a very few words. Kant based the assumption of the thing in itself, though concealed under various modes of expression, upon an inference from the law of causality — an inference that the empirical perception, or more accurately the *sensation*, in our organs of sense, from which it proceeds, must have an external cause. But according to his own account, which is correct, the law of causality is known to us *a priori*, consequently is a function of our intellect, and is thus of *subjective* origin; further, sensation itself, to which we here apply the law of causality, is undeniably *subjective*; and finally, even space, in which, by means of this application, we place the cause of this sensation as object, is a form of our intellect given *a priori*, and is consequently *subjective*. Therefore the whole empirical perception remains always upon a *subjective* foundation, as a mere process in us, and nothing entirely different from it and independent of it can be brought in as a *thing in itself*, or shown to be a necessary assumption. The empirical perception actually is and remains merely our idea: it is the world as idea. An inner nature of this we can only arrive at on

the entirely different path followed by me, by means of calling in the aid of self-consciousness, which proclaims the will as the inner nature of our own phenomenon; but then the thing in itself will be one which is *toto genere* different from the idea and its elements, as I have explained.

The great defect of the Kantian system in this point, which, as has been said, was soon pointed out, is an illustration of the truth of the beautiful Indian proverb: "No lotus without a stem." The erroneous deduction of the thing in itself is here the stem; yet only the method of the deduction, not the recognition of a thing in itself belonging to the given phenomenon. But this last was Fichte's misunderstanding of it, which could only happen because he was not concerned with truth, but with making a sensation for the furtherance of his individual ends. Accordingly he was bold and thoughtless enough to deny the thing in itself altogether, and to set up a system in which, not, as with Kant, the mere form of the idea, but also the matter, its whole content, was professedly deduced *a priori* from the subject. In doing this, he counted with perfect correctness upon the want of judgment and the stupidity of the public, which accepted miserable sophisms, mere hocus-pocus and senseless babble, for proofs; so that he succeeded in turning its attention from Kant to himself, and gave the direction to German philosophy in which it was afterwards carried further by Schelling, and ultimately reached its goal in the mad sophistry of Hegel.

I now return to the great mistake of Kant, already touched on above, that he has not properly separated perceptible and abstract knowledge, whereby an inextricable confusion has arisen which we have now to consider more closely. If he had sharply separated ideas of perception from conceptions merely thought *in abstracto*, he would have held these two apart, and in every case would have known with which of the two he had to do. This, however, was unfortunately not the case, although this accusation has not yet been openly made, and may thus perhaps be unexpected. His "object of experience," of which he is constantly speaking, the proper object of the categories, is not the idea of perception; neither is it the abstract conception, but it is different from both, and yet both at once, and is a perfect chimera. For, incredible as it may seem, he lacked either the wisdom or the honesty to come to an understanding with himself about this, and to explain distinctly to himself and others whether his "object of experience, *i.e.*, the knowledge produced by the application of the categories," is the idea of perception in space and time (my first class of ideas), or merely the abstract

conception. Strange as it is, there always runs in his mind something between the two, and hence arises the unfortunate confusion which I must now bring to light. For this end I must go through the whole theory of elements in a general way.

The "Transcendental Æsthetic" is a work of such extraordinary merit that it alone would have been sufficient to immortalise the name of Kant. Its proofs carry such perfect conviction, that I number its propositions among incontestable truths, and without doubt they are also among those that are richest in results, and are, therefore, to be regarded as the rarest thing in the world, a real and great discovery in metaphysics. The fact, strictly proved by him, that a part of our knowledge is known to us *a priori*, admits of no other explanation than that this constitutes the forms of our intellect; indeed, this is less an explanation than merely the distinct expression of the fact itself. For *a priori* means nothing else than "not gained on the path of experience, thus not come into us from without." But what is present in the intellect, and has not come from without, is just what belongs originally to the intellect itself, its own nature. Now if what is thus present in the intellect itself consists of the general mode or manner in which it must present all its objects to itself, this is just saying that what is thus present is the intellect's forms of knowing, *i.e.*, the mode, fixed once for all, in which it fulfils this its function. Accordingly, "knowledge *a priori*" and "the intellect's own forms" are at bottom only two expressions for the same things thus to a certain extent synonyms.

Therefore from the doctrine of the Transcendental Æsthetic I knew of nothing to take away, only of something to add. Kant did not carry out his thought to the end, especially in this respect, that he did not reject Euclid's whole method of demonstration, even after having said on p. 87; V. 120, that all geometrical knowledge has direct evidence from perception. It is most remarkable that one of Kant's opponents, and indeed the acutest of them, G. E. Schulze (*Kritik der theoretischen Philosophie*, ii. 241), draws the conclusion that from his doctrine an entirely different treatment of geometry from that which is actually in use would arise; and thus he thought to bring an apagogical argument against Kant, but, in fact, without knowing it, he only began the war against the method of Euclid. Let me refer to § 15 of the first book of this work.

After the full exposition of the universal *forms* of perception given in the Transcendental Æsthetic, one necessarily expects to receive some explanation as to its *content*, as to the way in which the *empirical* perception comes into our consciousness, how the knowledge of this whole world, which is for us so real and so important, arises in us. But the whole teaching of Kant contains really nothing more about this than the oft-repeated meaningless expression: "The empirical element in perception is *given* from without." Consequently here also from the *pure forms of perception* Kant arrives with one spring at *thinking* at the *Transcendental Logic*. Just at the beginning of the Transcendental Logic (Critique of Pure Reason, p. 50; V. 74), where Kant cannot avoid touching upon the content of the empirical perception, he takes the first false step; he is guilty of the πρωτον ψευδος. "Our knowledge," he says, "has two sources, receptivity of impressions and spontaneity of conceptions: the first is the capacity for receiving ideas, the second that of knowing an object through these ideas: through the first an *object* is given us, through the second it is thought." This is false; for according to it the *impression*, for which alone we have mere receptivity, which thus comes from without and alone is properly "given," would be already an *idea*, and indeed an *object*. But it is nothing more than a mere *sensation* in the organ of sense, and only by the application of the *understanding* (*i.e.*, of the law of causality) and the forms of perception, space and time, does our *intellect* change this mere *sensation* into an *idea*, which now exists as an object in space and time, and cannot be distinguished from the latter (the object) except in so far as we ask after the thing in itself, but apart from this is identical with it. I have explained this point fully in the essay on the principle of sufficient reason, § 21. With this, however, the work of the understanding and of the faculty of perception is completed, and no conceptions and no thinking are required in addition; therefore the brute also has these *ideas*. If conceptions are added, if thinking is added, to which spontaneity may certainly be attributed, then knowledge of *perception* is entirely abandoned, and a completely different class of ideas comes into consciousness, non-perceptible abstract conceptions. This is the activity of the *reason*, which yet obtains the whole content of its thinking only from the previous perception, and the comparison of it with other perceptions and conceptions. But thus Kant brings thinking into the perception, and lays the foundation for the inextricable confusion of

intuitive and abstract knowledge which I am now engaged in condemning. He allows the perception, taken by itself, to be without understanding, purely sensuous, and thus quite passive, and only through thinking (category of the understanding) does he allow an *object* to be apprehended: thus he brings *thought into the perception*. But then, again, the object of thinking is an individual real object; and in this way thinking loses its essential character of universality and abstraction, and instead of general conceptions receives individual things as its object: thus again he *brings perception into thinking*. From this springs the inextricable confusion referred to, and the consequences of this first false step extend over his whole theory of knowledge. Through the whole of his theory the utter confusion of the idea of perception with the abstract idea tends towards a something between the two which he expounds as the object of knowledge through the understanding and its categories, and calls this knowledge *experience*. It is hard to believe that Kant really figured to himself something fully determined and really distinct in this object of the understanding; I shall now prove this through the tremendous contradiction which runs through the whole Transcendental Logic, and is the real source of the obscurity in which it is involved.

In the "Critique of Pure Reason," p. 67-69; V. 92-94; p. 89, 90; V. 122, 123; further, V. 135, 139, 153, he repeats and insists: the understanding is no faculty of perception, its knowledge is not intuitive but discursive; the understanding is the faculty of judging (p. 69; V. 94), and a judgment is indirect knowledge, an idea of an idea (p. 68; V. 93); the understanding is the faculty of thinking, and thinking is knowledge through conceptions (p. 69; V. 94); the categories of the understanding are by no means the conditions under which objects are given in perception (p. 89; V. 122), and perception in no way requires the functions of thinking (p. 91; V. 123); our understanding can only think, not perceive (V. pp. 135, 139). Further, in the "Prolegomena," § 20, he says that perception, sensation, *perceptio*, belongs merely to the senses; judgment to the understanding alone; and in § 22, that the work of the senses is to perceive, that of the understanding to think, *i.e.*, to judge. Finally, in the "Critique of Practical Reason," fourth edition, p. 247; Rosenkranz's edition, p. 281, he says that the understanding is discursive; its ideas are thoughts, not perceptions. All this is in Kant's own words.

From this it follows that this perceptible world would exist for us even if we had no understanding at all; that it comes into our head in a quite inexplicable manner, which he constantly indicates by his strange expression the perception is *given*, without ever explaining this indefinite and metaphorical expression further.

Now all that has been quoted is contradicted in the most glaring manner by the whole of the rest of his doctrine of the understanding, of its categories, and of the possibility of experience as he explains it in the Transcendental Logic. Thus (Critique of Pure Reason, p. 79; V. 105), the understanding through its categories brings unity into the manifold of *perception*, and the pure conceptions of the understanding refer *a priori* to objects of *perception*. P. 94; V. 126, the "categories are the condition of experience, whether of perception, which is found in it, or of thought." V. p. 127, the understanding is the originator of experience. V. p. 128, the categories determine the *perception* of objects. V. p. 130, all that we present to ourselves as connected in the object (which is yet certainly something perceptible and not an abstraction), has been so connected by an act of the understanding. V. p. 135, the understanding is explained anew as the faculty of combining *a priori*, and of bringing the multiplicity of given ideas under the unity of apperception; but according to all ordinary use of words, apperception is not the thinking of a conception, but is *perception*. V. p. 136, we find a first principle of the possibility of all perception in connection with the understanding. V. p. 143, it stands as the heading, that all sense perception is conditioned by the categories. At the same place the *logical function of the judgment* also brings the manifold of given perceptions under an apperception in general, and the manifold of a given perception stands necessarily under the categories. V. p. 144, unity comes into perception, by means of the categories, through the understanding. V. p. 145, the thinking of the understanding is very strangely explained as synthetically combining, connecting, and arranging the manifold of perception. V. p. 161, experience is only possible through the categories, and consists in the connection of *sensations*, which, however, are just perceptions. V. p. 159, the categories are *a priori* knowledge of the objects of perception in general. Further, here and at V. p. 163 and 165, a chief doctrine of Kant's is given, this: *that the understanding first makes Nature possible*, because it prescribes laws for it *a priori*, and Nature adapts itself to the system of the understanding, and so on. Nature, however, is certainly

perceptible and not an abstraction; therefore, the understanding must be a faculty of perception. V. p. 168, it is said, the conceptions of the understanding are the principles of the possibility of experience, and the latter is the condition of phenomena in space and time in general; phenomena which, however, certainly exist in perception. Finally, p. 189-211; V. 232-265, the long proof is given (the incorrectness of which is shown in detail in my essay on the principle of sufficient reason, § 23) that the objective succession and also the coexistence of objects of experience are not sensuously apprehended, but are only brought into Nature by the understanding, and that Nature itself first becomes possible in this way. Yet it is certain that Nature, the course of events, and the coexistence of states, is purely perceptible, and no mere abstract thought.

I challenge every one who shares my respect towards Kant to reconcile these contradictions and to show that in his doctrine of the object of experience and the way it is determined by the activity of the understanding and its twelve functions, Kant thought something quite distinct and definite. I am convinced that the contradiction I have pointed out, which extends through the whole Transcendental Logic, is the real reason of the great obscurity of its language. Kant himself, in fact, was dimly conscious of the contradiction, inwardly combated it, but yet either would not or could not bring it to distinct consciousness, and therefore veiled it from himself and others, and avoided it by all kinds of subterfuges. This is perhaps also the reason why he made out of the faculties of knowledge such a strange complicated machine, with so many wheels, as the twelve categories, the transcendental synthesis of imagination, of the inner sense, of the transcendental unity of apperception, also the schematism of the pure conceptions of the understanding, &c., &c. And notwithstanding this great apparatus, not even an attempt is made to explain the perception of the external world, which is after all the principal fact in our knowledge; but this pressing claim is very meanly rejected, always through the same meaningless metaphorical expression: “The empirical perception is given us.” On p. 145 of the fifth edition, we learn further that the perception is given through the object; therefore the object must be something different from the perception.

If, now, we endeavour to investigate Kant’s inmost meaning, not clearly expressed by himself, we find that in reality such an object, different from the perception, but which is by no means a conception, is for him the proper

object for the understanding; indeed that it must be by means of the strange assumption of such an object, which cannot be presented in perception, that the perception first becomes experience. I believe that an old deeply-rooted prejudice in Kant, dead to all investigation, is the ultimate reason of the assumption of such an *absolute object*, which is an object in itself, *i.e.*, without a subject. It is certainly not the *perceived object*, but through the conception it is added to the perception by thought, as something corresponding to it; and now the perception is experience, and has value and truth, which it thus only receives through the relation to a conception (in diametrical opposition to my exposition, according to which the conception only receives value and truth from the perception). It is then the proper function of the categories to add on in thought to the perception this directly non-perceptible object. "The object is given only through perception, and is afterwards thought in accordance with the category" (Critique of Pure Reason, first edition, p. 399). This is made specially clear by a passage on p. 125 of the fifth edition: "Now the question arises whether conceptions *a priori* do not also come first as conditions under which alone a thing can be, not perceived certainly, but yet *thought* as an *object* in general," which he answers in the affirmative. Here the source of the error and the confusion in which it is involved shows itself distinctly. For the *object* as such exists always only for *perception* and in it; it may now be completed through the senses, or, when it is absent, through the imagination. What is thought, on the contrary, is always an universal non-perceptible *conception*, which certainly can be the conception of an object in general; but only indirectly by means of conceptions does thought relate itself to *objects*, which always are and remain *perceptible*. For our thinking is not able to impart reality to perceptions; this they have, so far as they are capable of it (empirical reality) of themselves; but it serves to bring together the common element and the results of perceptions, in order to preserve them, and to be able to use them more easily. But Kant ascribes the objects themselves to thought, in order to make experience and the objective world dependent upon *understanding*, yet without allowing understanding to be a faculty of *perception*. In this relation he certainly distinguishes perception from thought, but he makes particular things sometimes the object of perception and sometimes the object of thought. In reality, however, they are only the object of the former; our empirical perception is at once *objective*, just because it proceeds from the causal nexus. Things, not ideas

different from them, are directly its object. Particular things as such are perceived in the understanding and through the senses; the one-sided impression upon the latter is at once completed by the imagination. But, on the contrary, as soon as we pass over to thought, we leave the particular things, and have to do with general conceptions, which cannot be presented in perception, although we afterwards apply the results of our thought to particular things. If we hold firmly to this, the inadmissibleness of the assumption becomes evident that the perception of things only obtains reality and becomes experience through the thought of these very things applying its twelve categories. Rather in perception itself the empirical reality, and consequently experience, is already given; but the perception itself can only come into existence by the application to sensation of the knowledge of the causal nexus, which is the one function of the understanding. Perception is accordingly in reality intellectual, which is just what Kant denies.

Besides in the passages quoted, the assumption of Kant here criticised will be found expressed with admirable clearness in the "Critique of Judgment," § 36, just at the beginning; also in the "Metaphysical Principles of Natural Science," in the note to the first explanation of "Phenomenology." But with a *naïveté* which Kant ventured upon least of all with reference to this doubtful point, it is to be found most distinctly laid down in the book of a Kantian, Kiesewetter's "*Grundriss einer algemeinen Logik*," third edition, part i., p. 434 of the exposition, and part ii., § 52 and 53 of the exposition; similarly in Tieftrunk's "*Denklehre in rein Deutschem Gewande*" (1825). It there appears so clearly how those disciples who do not themselves think become a magnifying mirror of the errors of every thinker. Once having determined his doctrine of the categories, Kant was always cautious when expounding it, but his disciples on the contrary were quite bold, and thus exposed its falseness.

According to what has been said, the object of the categories is for Kant, not indeed the thing in itself, but yet most closely akin to it. It is the *object in itself*; it is an object that requires no subject; it is a particular thing, and yet not in space and time, because not perceptible; it is an object of thought, and yet not an abstract conception. Accordingly Kant really makes a triple division: (1.) the idea; (2.) the object of the idea; (3.) the thing in itself. The first belongs to the sensibility, which in its case, as in that of sensation, includes the pure forms of perception, space and time. The second belongs

to the understanding, which thinks it through its twelve categories. The third lies beyond the possibility of all knowledge. (In support of this, *cf.* Critique of Pure Reason, first edition, p. 108 and 109.) The distinction of the idea from the object of the idea is however unfounded; this had already been proved by Berkeley, and it appears from my whole exposition in the first book, especially chap. i. of the supplements; nay, even from Kant's own completely idealistic point of view in the first edition. But if we should not wish to count the object of the idea as belonging to the idea and identify it with the idea, it would be necessary to attribute it to the thing in itself: this ultimately depends on the sense which is attached to the word object. This, however, always remains certain, that, when we think clearly, nothing more can be found than idea and thing in itself. The illicit introduction of that hybrid, the object of the idea, is the source of Kant's errors; yet when it is taken away, the doctrine of the categories as conceptions *a priori* also falls to the ground; for they bring nothing to the perception, and are not supposed to hold good of the thing in itself, but by means of them we only think those "objects of the ideas," and thereby change ideas into experience. For every empirical perception is already experience; but every perception which proceeds from sensation is empirical: this sensation is related by the understanding, by means of its sole function (knowledge *a priori* of the law of causality), to its cause, which just on this account presents itself in space and time (forms of pure perception) as object of experience, material object, enduring in space through all time, yet as such always remains idea, as do space and time themselves. If we desire to go beyond this idea, then we arrive at the question as to the thing in itself, the answer to which is the theme of my whole work, as of all metaphysics in general. Kant's error here explained is connected with his mistake, which we condemned before, that he gives no theory of the origin of empirical perception, but, without saying more, treats it as *given*, identifying it with the mere sensation, to which he only adds the forms of intuition or perception, space and time, comprehending both under the name sensibility. But from these materials no objective idea arises: this absolutely demands the relation of the idea to its cause, thus the application of the law of causality, and thus understanding; for without this the sensation still remains always subjective, and does not take the form of an object in space, even if space is given with it. But according to Kant, the understanding must not be assigned to perception; it is supposed merely to *think*, so as to remain within the

transcendental logic. With this again is connected another mistake of Kant's: that he left it to me to adduce the only valid proof of the *a priori* nature of the law of causality which he rightly recognised, the proof from the possibility of objective empirical perception itself, and instead of it gives a palpably false one, as I have already shown in my essay on the principle of sufficient reason, § 23. From the above it is clear that Kant's "object of the idea" (2) is made up of what he has stolen partly from the idea (1), and partly from the thing in itself (3). If, in reality, experience were only brought about by the understanding applying its twelve different functions in order to *think* through as many conceptions *a priori*, the objects which were previously merely perceived, then every real thing would necessarily as such have a number of determinations, which, as given *a priori*, absolutely could not be thought away, just like space and time, but would belong quite essentially to the existence of the thing, and yet could not be deduced from the properties of space and time. But only one such determination is to be found — that of causality. Upon this rests materiality, for the essence of matter consists in action, and it is through and through causality (*cf.* Bk. II. ch. iv.) But it is materiality alone that distinguishes the real thing from the picture of the imagination, which is then only idea. For matter, as permanent, gives to the thing permanence through all time, in respect of its matter, while the forms change in conformity with causality. Everything else in the thing consists either of determinations of space or of time, or of its empirical properties, which are all referable to its activity, and are thus fuller determinations of causality. But causality enters already as a condition into the empirical perception, and this is accordingly a thing of the understanding, which makes even perception possible, and yet apart from the law of causality contributes nothing to experience and its possibility. What fills the old ontologies is, with the exception of what is given here, nothing more than relations of things to each other, or to our reflection, and a farrago of nonsense.

The language in which the doctrine of the categories is expressed affords an evidence of its baselessness. What a difference in this respect between the Transcendental Æsthetic and the Transcendental Analytic! In the former, what clearness, definiteness, certainty, firm conviction which is freely expressed and infallibly communicates itself! All is full of light, no dark lurking-places are left: Kant knows what he wants and knows that he is right. In the latter, on the other hand, all is obscure, confused, indefinite,

wavering, uncertain, the language anxious, full of excuses and appeals to what is coming, or indeed of suppression. Moreover, the whole second and third sections of the Deduction of the Pure Conceptions of the Understanding are completely changed in the second edition, because they did not satisfy Kant himself, and they have become quite different from the first edition, though not clearer. We actually see Kant in conflict with the truth in order to carry out his hypothesis which he has once fixed upon. In the Transcendental Æsthetic all his propositions are really proved from undeniable facts of consciousness, in the Transcendental Analytic, on the contrary, we find, if we consider it closely, mere assertions that thus it is and must be. Here, then, as everywhere, the language bears the stamp of the thought from which it has proceeded, for style is the physiognomy of the mind. We have still to remark, that whenever Kant wishes to give an example for the purpose of fuller explanation, he almost always takes for this end the category of causality, and then what he has said turns out correct; for the law of causality is indeed the real form of the understanding, but it is also its only form, and the remaining eleven categories are merely blind windows. The deduction of the categories is simpler and less involved in the first edition than in the second. He labours to explain how, according to the perception given by sensibility, the understanding produces experience by means of thinking the categories. In doing so, the words recognition, reproduction, association, apprehension, transcendental unity of apperception, are repeated to weariness, and yet no distinctness is attained. It is well worth noticing, however, that in this explanation he does not once touch upon what must nevertheless first occur to every one — the relation of the sensation to its external cause. If he did not intend this relation to hold good, he ought to have expressly denied it; but neither does he do this. Thus in this way he evades the point, and all the Kantians have in like manner evaded it. The secret motive of this is, that he reserves the causal nexus, under the name "ground of the phenomenon," for his false deduction of the thing in itself; and also that perception would become intellectual through the relation to the cause, which he dare not admit. Besides this, he seems to have been afraid that if the causal nexus were allowed to hold good between sensation and object, the latter would at once become the thing in itself, and introduce the empiricism of Locke. But this difficulty is removed by reflection, which shows us that the law of causality is of subjective origin, as well as the sensation itself; and besides this, our

own body also, inasmuch as it appears in space, already belongs to ideas. But Kant was hindered from confessing this by his fear of the Berkeleian idealism.

"The combination of the manifold of perception" is repeatedly given as the essential operation of the understanding, by means of its twelve categories. Yet this is never adequately explained, nor is it shown what this manifold of perception is before it is combined by the understanding. But time and space, the latter in all its three dimensions, are *continua*, *i.e.*, all their parts are originally not separate but combined. Thus, then, everything that exhibits itself in them (is given) appears originally as a *continuum*, *i.e.*, its parts appear already combined and require no adventitious combination of a manifold. If, however, some one should seek to interpret that combining of the manifold of perception by saying that I refer the different sense-impressions of one object to this one only — thus, for example, perceiving a bell, I recognise that what affects my eye as yellow, my hand as smooth and hard, my ear as sounding, is yet only one and the same body, — then I reply that this is rather a consequence of the knowledge *a priori* of the causal nexus (this actual and only function of the understanding), by virtue of which all those different effects upon my different organs of sense yet lead me only to one common cause of them, the nature of the body standing before me, so that my understanding, in spite of the difference and multiplicity of the effects, still apprehends the unity of the cause as a single object, which just on that account exhibits itself in perception. In the beautiful recapitulation of his doctrine which Kant gives at p. 719-726 or V. 747-754 of the "Critique of Pure Reason," he explains the categories, perhaps more distinctly than anywhere else, as "the mere rule of the synthesis of that which empirical apprehension has given *a posteriori*." It seems as if here he had something in his mind, such as that, in the construction of the triangle, the angles give the rule for the composition of the lines; at least by this image one can best explain to oneself what he says of the function of the categories. The preface to the "Metaphysical First Principles of Natural Science" contains a long note which likewise gives an explanation of the categories, and says that they "differ in no respect from the formal acts of the understanding in judging," except that in the latter subject and predicate can always change places; then the judgment in general is defined in the same passage as "an act through which given ideas first become knowledge of an object." According to this, the brutes, since

they do not judge, must also have no knowledge of objects. In general, according to Kant, there are only conceptions of objects, no perceptions. I, on the contrary, say: Objects exist primarily only for perception, and conceptions are always abstractions from this perception. Therefore abstract thinking must be conducted exactly according to the world present in perception, for it is only their relation to this that gives content to conceptions; and we must assume for the conceptions no other *a priori* determined form than the faculty of reflection in general, the nature of which is the construction of conceptions, *i.e.*, of abstract non-perceptible ideas, which constitutes the sole function of the *reason*, as I have shown in the first book. I therefore require that we should reject eleven of the categories, and only retain that of causality, and yet that we should see clearly that its activity is indeed the condition of empirical perception, which accordingly is not merely sensuous but intellectual, and that the object so perceived, the object of experience, is one with the idea, from which there remains nothing to distinguish except the thing in itself.

After repeated study of the "Critique of Pure Reason" at different periods of my life, a conviction has forced itself upon me with regard to the origin of the Transcendental Logic, which I now impart as very helpful to an understanding of it. Kant's only discovery, which is based upon objective comprehension and the highest human thought, is the *apperçu* that time and space are known by us *a priori*. Gratified by this happy hit, he wished to pursue the same vein further, and his love of architectonic symmetry afforded him the clue. As he had found that a pure intuition or perception *a priori* underlay the empirical *perception* as its condition, he thought that in the same way certain *pure conceptions* as presuppositions in our faculty of knowledge must lie at the foundation of the empirically obtained *conceptions*, and that real empirical thought must be only possible through a pure thought *a priori*, which, however, would have no objects in itself, but would be obliged to take them from perception. So that as the *Transcendental Æsthetic* establishes an *a priori* basis of mathematics, there must, he supposed, also be a similar basis for logic; and thus, then for the sake of symmetry, the former received a pendant in a *Transcendental Logic*. From this point onwards Kant was no more free, no more in the position of purely, investigating and observing what is present in consciousness; but he was guided by an assumption and pursued a purpose — the purpose of finding what he assumed, in order to add to the Transcendental Æsthetic so

happily discovered a Transcendental Logic analogous to it, and thus symmetrically corresponding to it, as a second storey. Now for this purpose he hit upon the table of judgments, out of which he constructed, as well as he could, the table of categories, the doctrine of twelve pure *a priori* conceptions, which are supposed to be the conditions of our *thinking* those very *things* the *perception* of which is conditioned by the two *a priori* forms of sensibility: thus a *pure understanding* now corresponded symmetrically to a *pure sensibility*. Then another consideration occurred to him, which offered a means of increasing the plausibility of the thing, by the assumption of the *schematism* of the pure conceptions of the understanding. But just through this the way in which his procedure had, unconsciously indeed, originated betrayed itself most distinctly. For because he aimed at finding something *a priori* analogous to every empirical function of the faculty of knowledge, he remarked that between our empirical perception and our empirical thinking, conducted in abstract non-perceptible conceptions, a connection very frequently, though not always, takes place, because every now and then we try to go back from abstract thinking to perception; but try to do so merely in order really to convince ourselves that our abstract thought has not strayed far from the safe ground of perception, and perhaps become exaggeration, or, it may be, mere empty talk; much in the same way as, when we are walking in the dark, we stretch out our hand every now and then to the guiding wall. We go back, then, to the perception only tentatively and for the moment, by calling up in imagination a perception corresponding to the conceptions which are occupying us at the time — a perception which can yet never be quite adequate to the conception, but is merely a temporary *representative* of it. I have already adduced what is needful on this point in my essay on the principle of sufficient reason, § 28. Kant calls a fleeting phantasy of this kind a schema, in opposition to the perfected picture of the imagination. He says it is like a monogram of the imagination, and asserts that just as such a schema stands midway between our abstract thinking of empirically obtained conceptions, and our clear perception which comes to us through the senses, so there are *a priori schemata of the pure conceptions of the understanding* between the faculty of perception *a priori* of pure sensibility and the faculty of thinking *a priori* of the pure understanding (thus the categories). These schemata, as monograms of the pure imagination *a priori*, he describes one by one, and assigns to each of them its corresponding category, in the wonderful

“Chapter on the Schematism of the Pure Conceptions of the Understanding,” which is noted as exceedingly obscure, because no man has ever been able to make anything out of it. Its obscurity, however, vanishes if it is considered from the point of view here indicated, but there also comes out more clearly in it than anywhere else the intentional nature of Kant’s procedure, and of the determination formed beforehand of finding what would correspond to the analogy, and could assist the architectonic symmetry; indeed this is here the case to such a degree as to be almost comical. For when he assumes schemata of the pure (empty) *a priori* conceptions of the understanding (categories) analogous to the empirical schemata (or representatives through the fancy of our actual conceptions), he overlooks the fact that the end of such schemata is here entirely wanting, For the end of the schemata in the case of empirical (real) thinking is entirely connected with the *material content* of such conceptions. For since these conceptions are drawn from empirical perception, we assist and guide ourselves when engaged in abstract thinking by now and then casting a momentary glance back at the perception out of which the conceptions are framed, in order to assure ourselves that our thought has still real content. This, however, necessarily presupposes that the conceptions which occupy us are sprung from perception, and it is merely a glance back at their material content, indeed a mere aid to our weakness. But in the case of *a priori* conceptions which as yet have no content at all, clearly this is necessarily omitted. For these conceptions are not sprung from perception, but come to it from within, in order to receive a content first from it. Thus they have as yet nothing on which they could look back. I speak fully upon this point, because it is just this that throws light upon the secret origin of the Kantian philosophising, which accordingly consists in this, that Kant, after the happy discovery of the two forms of intuition or perception *a priori*, exerted himself, under the guidance of the analogy, to prove that for every determination of our empirical knowledge there is an *a priori* analogue, and this finally extended, in the schemata, even to a mere psychological fact. Here the apparent depth and the difficulty of the exposition just serve to conceal from the reader that its content remains a wholly undemonstrable and merely arbitrary assumption. But he who has penetrated at last to the meaning of such an exposition is then easily induced to mistake this understanding so painfully attained for a conviction of the truth of the matter. If, on the contrary, Kant had kept himself here as

unprejudiced and purely observant as in the discovery of *a priori* intuition or perception, he must have found that what is added to the pure intuition or perception of space and time, if an empirical perception arises from it, is on the one hand the sensation, and on the other hand the knowledge of causality, which changes the mere sensation into objective empirical perception, but just on this account is not first derived and learned from sensation, but exists *a priori*, and is indeed the form and function of the pure understanding. It is also, however, its sole form and function, yet one so rich in results that all our empirical knowledge rests upon it. If, as has often been said, the refutation of an error is only complete when the way it originated has been psychologically demonstrated, I believe I have achieved this, with regard to Kant's doctrine of the categories and their schemata, in what I have said above.

After Kant had thus introduced such great errors into the first simple outlines of a theory of the faculty of perception, he adopted a variety of very complicated assumptions. To these belongs first of all the synthetic unity of apperception: a very strange thing, very strangely explained. "The *I think* must be able to accompany all my ideas." Must — be able: this is a problematic-apodictic enunciation; in plain English, a proposition which takes with one hand what it gives with the other. And what is the meaning of this carefully balanced proposition? That all knowledge of ideas is thinking? That is not the case: and it would be dreadful; there would then be nothing but abstract conceptions, or at any rate a pure perception free from reflection and will, such as that of the beautiful, the deepest comprehension of the true nature of things, *i.e.*, of their Platonic Ideas. And besides, the brutes would then either think also, or else they would not even have ideas. Or is the proposition perhaps intended to mean: no object without a subject? That would be very badly expressed by it, and would come too late. If we collect Kant's utterances on the subject, we shall find that what he understands by the synthetic unity of apperception is, as it were, the extensionless centre of the sphere of all our ideas, whose radii converge to it. It is what I call the subject of knowing, the correlative of all ideas, and it is also that which I have fully described and explained in the 22d chapter of the Supplements, as the focus in which the rays of the activity of the brain converge. Therefore, to avoid repetition, I now refer to that chapter.

That I reject the whole doctrine of the categories, and reckon it among the groundless assumptions with which Kant burdened the theory of knowledge, results from the criticism given above; and also from the proof of the contradictions in the Transcendental Logic, which had their ground in the confusion of perception and abstract knowledge; also further from the proof of the want of a distinct and definite conception of the nature of the understanding and of the reason, instead of which we found in Kant's writings only incoherent, inconsistent, insufficient, and incorrect utterances with regard to these two faculties of the mind. Finally, it results from the explanations which I myself have given of these faculties of the mind in the first book and its Supplements, and more fully in the essay on the principle of sufficient reason, § 21, 26, and 34, — explanations which are very definite and distinct, which clearly follow from the consideration of the nature of our knowledge, and which completely agree with the conceptions of those two faculties of knowledge that appear in the language and writings of all ages and all nations, but were not brought to distinctness. Their defence against the very different exposition of Kant has, for the most part, been given already along with the exposure of the errors of that exposition. Since, however, the table of judgments, which Kant makes the foundation of his theory of thinking, and indeed of his whole philosophy, has, in itself, as a whole, its correctness, it is still incumbent upon me to show how these universal forms of all judgment arise in our faculty of knowledge, and to reconcile them with my exposition of it. In this discussion I shall always attach to the concepts understanding and reason the sense given them in my explanation, which I therefore assume the reader is familiar with.

An essential difference between Kant's method and that which I follow lies in this, that he starts from indirect, reflected knowledge, while I start from direct or intuitive knowledge. He may be compared to a man who measures the height of a tower by its shadow, while I am like him who applies the measuring-rule directly to the tower itself. Therefore, for him philosophy is a science *of* conceptions, but for me it is a science *in* conceptions, drawn from knowledge of perception, the one source of all evidence, and comprehended and made permanent in general conceptions. He passes over this whole world of perception which surrounds us, so multifarious and rich in significance, and confines himself to the forms of abstract thinking; and, although he never expressly says so, this procedure

is founded on the assumption that reflection is the ectype of all perception, that, therefore, all that is essential in perception must be expressed in reflection, and expressed in very contracted forms and outlines, which are thus easily surveyed. According to this, what is essential and conformable to law in abstract knowledge would, as it were, place in our hands all the threads by which the varied puppet-show of the world of perception is set in motion before our eyes. If Kant had only distinctly expressed this first principle of his method, and then followed it consistently, he would at least have been obliged to separate clearly the intuitive from the abstract, and we would not have had to contend with inextricable contradictions and confusions. But from the way in which he solves his problem we see that that fundamental principle of his method was only very indistinctly present to his mind, and thus we have still to arrive at it by conjecture even after a thorough study of his philosophy.

Now as concerns the specified method and fundamental maxim itself, there is much to be said for it, and it is a brilliant thought. The nature of all science indeed consists in this, that we comprehend the endless manifold of perceptible phenomena under comparatively few abstract conceptions, and out of these construct a system by means of which we have all those phenomena completely in the power of our knowledge, can explain the past and determine the future. The sciences, however, divide the wide sphere of phenomena among them according to the special and manifold classes of the latter. Now it was a bold and happy thought to isolate what is absolutely essential to the conceptions as such and apart from their content, in order to discover from these forms of all thought found in this way what is essential to all intuitive knowledge also, and consequently to the world as phenomenon in general; and because this would be found *a priori* on account of the necessity of those forms of thought, it would be of subjective origin, and would just lead to the ends Kant had in view. Here, however, before going further, the relation of reflection to knowledge of perception ought to have been investigated (which certainly presupposes the clear separation of the two, which was neglected by Kant). He ought to have inquired in what way the former really repeats and represents the latter, whether quite pure, or changed and to some extent disguised by being taken up into its special forms (forms of reflection); whether the form of abstract reflective knowledge becomes more determined through the form of knowledge of perception, or through the nature or constitution which

unalterably belongs to itself, *i.e.*, to reflective knowledge, so that even what is very heterogeneous in intuitive knowledge can no longer be distinguished when it has entered reflective knowledge, and conversely many distinctions of which we are conscious in the reflective method of knowledge have also sprung from this knowledge itself, and by no means point to corresponding differences in intuitive knowledge. As the result of this investigation, however, it would have appeared that knowledge of perception suffers very nearly as much change when it is taken up into reflection as food when it is taken into the animal organism whose forms and compounds are determined by itself, so that the nature of the food can no longer be recognised from the result they produce. Or (for this is going a little too far) at least it would have appeared that reflection is by no means related to knowledge of perception as the reflection in water is related to the reflected objects, but scarcely even as the mere shadow of these objects stands to the objects themselves; which shadow repeats only a few external outlines, but also unites the most manifold in the same form and presents the most diverse through the same outline; so that it is by no means possible, starting from it, to construe the forms of things with completeness and certainty.

The whole of reflective knowledge, or the reason, has only one chief form, and that is the abstract conception. It is proper to the reason itself, and has no direct necessary connection with the world of perception, which therefore exists for the brutes entirely without conceptions, and indeed, even if it were quite another world from what it is, that form of reflection would suit it just as well. But the combination of conceptions for the purpose of judging has certain definite and normal forms, which have been found by induction, and constitute the table of judgments. These forms are for the most part deducible from the nature of reflective knowledge itself, thus directly from the reason, because they spring from the four laws of thought (called by me metalogical truths) and the *dictum de omni et nullo*. Certain others of these forms, however, have their ground in the nature of knowledge of perception, thus in the understanding; yet they by no means point to a like number of special forms of the understanding, but can all be fully deduced from the sole function which the understanding has — the direct knowledge of cause and effect. Lastly, still others of these forms have sprung from the concurrence and combination of the reflective and intuitive modes of knowledge, or more properly from the assumption of the latter into the former. I shall now go through the moments of the judgment one

by one, and point out the origin of each of them in the sources referred to; and from this it follows of itself that a deduction of categories from them is wanting, and the assumption of this is just as groundless as its exposition was found to be entangled and self-conflicting.

1. The so-called *Quantity* of judgments springs from the nature of concepts as such. It thus has its ground in the reason alone, and has absolutely no direct connection with the understanding and with knowledge of perception. It is indeed, as is explained at length in the first book, essential to concepts, as such, that they should have an extent, a sphere, and the wider, less determined concept includes the narrower and more determined. The latter can therefore be separated from the former, and this may happen in two ways, — either the narrower concept may be indicated as an indefinite part of the wider concept in general, or it may be defined and completely separated by means of the addition of a special name. The judgment which carries out this operation is in the first case called a particular, and in the second case an universal judgment. For example, one and the same part of the sphere of the concept tree may be isolated through a particular and through an universal judgment, thus— "Some trees bear gall-nuts," or "All oaks bear gall-nuts." One sees that the difference of the two operations is very slight; indeed, that the possibility of it depends upon the richness of the language. Nevertheless, Kant has explained this difference as disclosing two fundamentally different actions, functions, categories of the pure understanding which determines experience *a priori* through them.

Finally, a concept may also be used in order to arrive by means of it at a definite particular idea of perception, from which, as well as from many others, this concept itself is drawn; this happens in the singular judgment. Such a judgment merely indicates the boundary-line between abstract knowledge and knowledge of perception, and passes directly to the latter, "This tree here bears gall-nuts." Kant has made of this also a special category.

After all that has been said there is no need of further polemic here.

2. In the same way the *Quality* of the judgment lies entirely within the province of reason, and is not an adumbration of any law of that understanding which makes perception possible, *i.e.*, it does not point to it. The nature of abstract concepts, which is just the nature of the reason itself objectively comprehended, carries with it the possibility of uniting and

separating their spheres, as was already explained in the first book, and upon this possibility, as their presupposition, rest the universal laws of thought of identity and contradiction, to which I have given the name of *metalogical* truths, because they spring purely from the reason, and cannot be further explained. They determine that what is united must remain united, and what is separated must remain separate, thus that what is established cannot at the same time be also abolished, and thus they presuppose the possibility of the combination and separation of spheres, *i.e.*, of judgment. This, however, lies, according to its *form*, simply and solely in the reason, and this *form* has not, like the *content* of the judgments, been brought over from the perceptible knowledge of the understanding, and therefore there is no correlative or analogue of it to be looked for there. After the perception has been brought about through the understanding and for the understanding, it exists complete, subject to no doubt nor error, and therefore knows neither assertion nor denial; for it expresses itself, and has not, like the abstract knowledge of the reason, its value and content in its mere relation to something outside of it, according to the principle of the ground of knowing. It is, therefore, pure reality; all negation is foreign to its nature, can only be added on through reflection, and just on this account remains always in the province of abstract thought.

To the affirmative and negative Kant adds the infinite judgment, making use of a crotchet of the old scholastics, an ingeniously invented stop-gap, which does not even require to be explained, a blind window, such as many others he made for the sake of his architectonic symmetry.

3. Under the very wide conception of *Relation* Kant has brought three entirely different properties of judgments, which we must, therefore, examine singly, in order to recognise their origin.

(*a.*) The *hypothetical judgment* in general is the abstract expression of that most universal form of all our knowledge, the principle of sufficient reason. In my essay on this principle, I already showed in 1813 that it has four entirely different meanings, and in each of these originally originates in a different faculty of knowledge, and also concerns a different class of ideas. It clearly follows from this, that the source of the hypothetical judgment in general, of that universal form of thought, cannot be, as Kant wishes to make it, merely the understanding and its category of causality; but that the law of causality which, according to my exposition, is the one form of knowledge of the pure understanding, is only one of the forms of

that principle which embraces all pure or *a priori* knowledge — the principle of sufficient reason — which, on the other hand, in each of its meanings has this hypothetical form of judgment as its expression. We see here, however, very distinctly how kinds of knowledge which are quite different in their origin and significance yet appear, if thought *in abstracto* by the reason, in one and the same form of combination of concepts and judgments, and then in this form can no longer be distinguished, but, in order to distinguish them, we must go back to knowledge of perception, leaving abstract knowledge altogether. Therefore the path which was followed by Kant, starting from the point of view of abstract knowledge, to find the elements and the inmost spring of intuitive knowledge also, was quite a wrong one. For the rest, my whole introductory essay on the principle of sufficient reason is, to a certain extent, to be regarded merely as a thorough exposition of the significance of the hypothetical form of judgment; therefore I do not dwell upon it longer here.

(*b.*) The form of the *categorical judgment* is nothing but the form of judgment in general, in its strictest sense. For, strictly speaking, judging merely means thinking, the combination of, or the impossibility of combining, the spheres of the concepts. Therefore the hypothetical and the disjunctive combination are properly no special forms of the judgment; for they are only applied to already completed judgments, in which the combination of the concepts remains unchanged the categorical. But they again connect these judgments, for the hypothetical form expresses their dependence upon each other, and the disjunctive their incompatibility. Mere concepts, however, have only *one* class of relations to each other, those which are expressed in the categorical judgment. The fuller determination, or the sub-species of this relation, are the intersection and the complete separateness of the concept-spheres, *i.e.*, thus affirmation and negation; out of which Kant has made special categories, under quite a different title, that of *quality*. Intersection and separateness have again sub-species, according as the spheres lie within each other entirely, or only in part, a determination which constitutes the *quantity* of the judgments; out of which Kant has again made a quite special class of categories. Thus he separates what is very closely related, and even identical, the easily surveyed modifications of the one possible relation of mere concepts to each other, and, on the other hand, unites what is very different under this title of relation.

Categorical judgments have as their metalogical principle the laws of thought of identity and contradiction. But the *ground* of the connection of the concept-spheres which gives *truth* to the judgment, which is nothing but this connection, may be of very different kinds; and, according to this, the truth of the judgment is either logical, or empirical, or metaphysical, or metalogical, as is explained in the introductory essay, § 30-33, and does not require to be repeated here. But it is apparent from this how very various the direct cognitions may be, all of which exhibit themselves in the abstract, through the combination of the spheres of two concepts, as subject and predicate, and that we can by no means set up the sole function of the understanding as corresponding to them and producing them. For example, the judgments, "Water boils, the sine measures the angle, the will resolves, business distracts, distinction is difficult," express through the same logical form the most different kinds of relations; but from this we obtain the right, however irregular the beginning may be, of placing ourselves at the standpoint of abstract knowledge to analyse direct intuitive knowledge. For the rest, the categorical judgment springs from knowledge of the understanding proper, in my sense, only when causation is expressed by it; this is, however, the case in all judgments which refer to a physical quality. For if I say, "This body is heavy, hard, fluid, green, sour, alkaline, organic, &c., &c.," this always refers to its effect, and thus is knowledge which is only possible through the pure understanding. Now, after this, like much which is quite different from it (for example, the subordination of very abstract concepts), has been expressed in the abstract through subject and predicate, these mere relations of concepts have been transferred back to knowledge of perception, and it has been supposed that the subject and predicate of the judgment must have a peculiar and special correlative in perception, substance and accident. But I shall show clearly further on that the conception substance has no other true content than that of the conception matter. Accidents, however, are quite synonymous with kinds of effects, so that the supposed knowledge of substance and accident is never anything more than the knowledge of cause and effect by the understanding. But the special manner in which the idea of matter arises is explained partly in § 4 of the first book, and still more clearly in the essay on the principle of sufficient reason at the end of § 21, p. 77 (3d ed., p. 82), and in some respects we shall see it still more closely when we investigate the principle of the permanence of substance.

(*c.*) *Disjunctive judgments* spring from the law of thought of excluded third, which is a metalogical truth; they are, therefore, entirely the property of the reason, and have not their origin in the understanding. The deduction of the category of community or *reciprocity* from them is, however, a glaring example of the violence which Kant sometimes allowed to be done to truth, merely in order to satisfy his love of architectonic symmetry. The illegitimacy of that deduction has already often been justly condemned and proved upon various grounds, especially by G. E. Schulze in his "*Kritik der theoretischen Philosophie*," and by Berg in his "*Epikritik der Philosophie*." What real analogy is there, indeed, between the problematical determination of a concept by disjunctive predicates and the thought of reciprocity? The two are indeed absolutely opposed, for in the disjunctive judgment the actual affirmation of one of the two alternative propositions is also necessarily the negation of the other; if, on the other hand, we think two things in the relation of reciprocity, the affirmation of one is also necessarily the affirmation of the other, and *vice versa*. Therefore, unquestionably, the real logical analogue of reciprocity is the vicious circle, for in it, as nominally in the case of reciprocity, what is proved is also the proof, and conversely. And just as logic rejects the vicious circle, so the conception of reciprocity ought to be banished from metaphysics. For I now intend, quite seriously, to prove that there is no reciprocity in the strict sense, and this conception, which people are so fond of using, just on account of the indefiniteness of the thought, is seen, if more closely considered, to be empty, false, and invalid. First of all, the reader must call to mind what causality really is, and to assist my exposition, see upon this subject § 20 of the introductory essay, also my prize-essay on the freedom of the will, chap. iii. p. 27 *seq.*, and lastly the fourth chapter of the second book of this work. Causality is the law according to which the conditions or states of matter which appear determine their position in time. Causality has to do merely with conditions or states, indeed, properly, only with *changes*, and neither with matter as such, nor with permanence without change. *Matter*, as such, does not come under the law of causality, for it neither comes into being nor passes away; thus neither does the whole *thing*, as we commonly express ourselves, come under this law, but only the *conditions* or *states* of matter. Further, the law of causality has nothing to do with *permanence*, for where nothing changes there is no producing of *effects* and no causality, but a continuing quiet condition or state. But if, now, such a state is changed, then

the new state is either again permanent or it is not, but immediately introduces a third state, and the necessity with which this happens is just the law of causality, which is a form of the principle of sufficient reason, and therefore cannot be further explained, because the principle of sufficient reason is the principle of all explanation and of all necessity. From this it is clear that cause and effect stand in intimate connection with, and necessary relation to, the *course of time*. Only because the state A. precedes in time the state B., and their succession is necessary and not accidental, *i.e.*, no mere sequence but a consequence — only because of this is the state A. cause and the state B. effect. The conception *reciprocity*, however, contains this, that both are cause and both are effect of each other; but this really amounts to saying that each of the two is the earlier and also the later; thus it is an absurdity. For that both states are simultaneous, and indeed necessarily simultaneous, cannot be admitted, because, as necessarily belonging to each other and existing at the same time, they constitute only *one* state. For the permanence of this state there is certainly required the continued existence of all its determinations, but we are then no longer concerned with change and causality, but with duration and rest, and nothing further is said than that if *one* determination of the whole state be changed, the new state which then appears cannot continue, but becomes the cause of the change of all the other determinations of the first state, so that a new third state appears; which all happens merely in accordance with the simple law of causality, and does not establish a *new* law, that of reciprocity.

I also definitely assert that the conception *reciprocity* cannot be supported by a single example. Everything that one seeks to pass off as such is either a state of rest, to which the conception of causality, which has only significance with reference to changes, finds no application at all, or else it is an alternating succession of states of the same name which condition each other, for the explanation of which simple causality is quite sufficient. An example of the first class is afforded by a pair of scales brought to rest by equal weights. Here there is no effect produced, for there is no change; it is a state of rest; gravity acts, equally divided, as in every body which is supported at its centre of gravity, but it cannot show its force by any effect. That the taking away of one weight produces a second state, which at once becomes the cause of the third, the sinking of the other scale, happens according to the simple law of cause and effect, and requires no special

category of the understanding, and not even a special name. An example of the second class is the continuous burning of a fire. The combination of oxygen with the combustible body is the cause of heat, and heat, again, is the cause of the renewed occurrence of the chemical combination. But this is nothing more than a chain of causes and effects, the links of which have alternately *the same name*. The burning, A., produces free heat, B., this produces new burning, C. (*i.e.*, a new effect which has the same name as the cause A., but is not individually identical with it), this produces new heat, D. (which is not really identical with the effect B., but only according to the concept, *i.e.*, it has the same name), and so on indefinitely. A good example of what in ordinary life is called reciprocity is afforded by a theory about deserts given by Humboldt (*Ansichten der Natur*, 2d ed., vol. ii. p. 79). In the sandy deserts it does not rain, but it rains upon the wooded mountains surrounding them. The cause is not the attraction of the clouds by the mountains; but it is the column of heated air rising from the sandy plain which prevents the particles of vapour from condensing, and drives the clouds high into the heavens. On the mountains the perpendicular rising stream of air is weaker, the clouds descend, and the rainfall ensues in the cooler air. Thus, want of rain and the absence of plants in the desert stand in the relation of reciprocity; it does not rain because the heated sand-plain sends out more heat; the desert does not become a steppe or prairie because it does not rain. But clearly we have here again, as in the example given above, only a succession of causes and effects of the same names, and throughout nothing essentially different from simple causality. This is also the case with the swinging of the pendulum, and indeed also with the self-conservation of the organised body, in which case likewise every state introduces a new one, which is of the same kind as that by which it was itself brought about, but individually is new. Only here the matter is complicated, because the chain no longer consists of links of two kinds, but of many kinds, so that a link of the same name only recurs after several others have intervened. But we always see before us only an application of the single and simple law of causality which gives the rule to the sequence of states, but never anything which must be comprehended by means of a new and special function of the understanding.

Or is it perhaps advanced in support of the conception of reciprocity that action and reaction are equal? But the reason of this is what I urge so strongly and have fully explained in the essay on the principle of sufficient

reason, that the cause and the effect are not two bodies, but two successive states of bodies, consequently each of the two states implicates all bodies concerned; thus the effect, *i.e.*, the newly appearing state, for example, in the case of an impulse, extends to both bodies in the same proportion; therefore the body impelled produces just as great a change in the body impelling as it itself sustains (each in proportion to its mass and velocity). If one pleases to call this reciprocity, then absolutely every effect is a reciprocal effect, and no new conception is introduced on this account, still less does it require a new function of the understanding, but we only have a superfluous synonym for causality. But Kant himself, in a moment of thoughtlessness, exactly expressed this view in the "Metaphysical First Principles of Natural Science" at the beginning of the proof of the fourth principle of mechanics: "All external effect in the world is reciprocal effect." How then should different functions lie *a priori* in the understanding for simple causality and for reciprocity, and, indeed, how should the real succession of things only be possible and knowable by means of the first, and their co-existence by means of the second? According to this, if all effect is reciprocal effect, succession and simultaneity would be the same thing, and therefore everything in the world would take place at the same moment. If there were true reciprocity, then perpetual motion would also be possible, and indeed *a priori* certain; but it is rather the case that the *a priori* conviction that there is no true reciprocity, and no corresponding form of the understanding, is the ground of the assertion that perpetual motion is impossible.

Aristotle also denies reciprocity in the strict sense; for he remarks that two things may certainly be reciprocal causes of each other, but only if this is understood in a different sense of each of them; for example, that one acts upon the other as the motive, but the latter acts upon the former as the cause of its movement. We find in two passages the same words: Physic., lib. ii. c. 3, and Metaph., lib. v. c. 2. Εστι δε τινα και αλληλων αιτια; οἱον το πονειν αιτιον της ευεξιας, και αὑτη του πονειν; αλλ᾽ ου τον αυτον τροπον, αλλα το μεν ὡς τελος, το δε ὡς αρχη κινησεως. (*Sunt præterea quæ sibi sunt mutuo causæ, ut exercitium bonæ habitudinis, et hæc exercitii: at non eodem modo, sed hæc ut finis, aliud ut principium motus.*) If, besides this, he had accepted a reciprocity proper, he would have introduced it here, for in both passages he is concerned with enumerating all the possible kinds of causes.

In the *Analyt. post.*, lib. ii. c. 11, he speaks of a circle of causes and effects, but not of reciprocity.

4. The categories of *Modality* have this advantage over all others, that what is expressed through each of them really corresponds to the form of judgment from which it is derived; which with the other categories is scarcely ever the case, because for the most part they are deduced from the forms of judgment with the most capricious violence.

Thus that it is the conceptions of the possible, the actual, and the necessary which occasion the problematic, assertatory, and apodictic forms of judgment, is perfectly true; but that those conceptions are special, original forms of knowledge of the understanding which cannot be further deduced is not true. On the contrary, they spring from the single original form of all knowledge, which is, therefore, known to us *a priori*, the principle of sufficient reason; and indeed out of this the knowledge of *necessity* springs directly. On the other hand, it is only because reflection is applied to this that the conceptions of contingency, possibility, impossibility, and actuality arise. Therefore all these do not by any means spring from *one* faculty of the mind, the understanding, but arise through the conflict of abstract and intuitive knowledge, as will be seen directly.

I hold that to be necessary and to be the consequent of a given reason are absolutely interchangeable notions, and completely identical. We can never know, nor even think, anything as necessary, except so far as we regard it as the consequent of a given reason; and the conception of necessity contains absolutely nothing more than this dependence, this being established through something else, and this inevitable following from it. Thus it arises and exists simply and solely through the application of the principle of sufficient reason. Therefore, there is, according to the different forms of this principle, a physical necessity (the effect from the cause), a logical (through the ground of knowing, in analytical judgments, syllogisms, &c.), a mathematical (according to the ground of being in time and space), and finally a practical necessity, by which we intend to signify not determination through a pretended categorical imperative, but the necessary occurrence of an action according to the motives presented, in the case of a given empirical character. But everything necessary is only so relatively, that is, under the presupposition of the reason from which it follows; therefore absolute necessity is a contradiction. With regard to the rest, I refer to § 49 of the essay on the principle of sufficient reason.

The contradictory opposite, *i.e.*, the denial of necessity, is *contingency*. The content of this conception is, therefore, negative — nothing more than this: absence of the connection expressed by the principle of sufficient reason. Consequently the contingent is also always merely relative. It is contingent in relation to something which is not its reason. Every object, of whatever kind it may be — for example, every event in the actual world — is always at once necessary and contingent, *necessary* in relation to the *one* condition which is its cause: *contingent* in relation to everything else. For its contact in time and space with everything else is a mere coincidence without necessary connection: hence also the words chance, συμπτωμα, *contingens*. Therefore an absolute contingency is just as inconceivable as an absolute necessity. For the former would be simply an object which stood to no other in the relation of consequent to its reason. But the inconceivability of such a thing is just the content of the principle of sufficient reason negatively expressed, and therefore this principle must first be upset before we can think an absolute contingency; and even then it itself would have lost all significance, for the conception of contingency has meaning only in relation to that principle, and signifies that two objects do not stand to each other in the relation of reason and consequent.

In nature, which consists of ideas of perception, everything that happens is necessary; for it proceeds from its cause. If, however, we consider this individual with reference to everything else which is not its cause, we know it as contingent; but this is already an abstract reflection. Now, further, let us abstract entirely from a natural object its causal relation to everything else, thus its necessity and its contingency; then this kind of knowledge comprehends the conception of the *actual*, in which one only considers the *effect*, without looking for the cause, in relation to which one would otherwise have to call it *necessary*, and in relation to everything else *contingent*. All this rests ultimately upon the fact that the *modality* of the judgment does not indicate so much the objective nature of things as the relation of our knowledge to them. Since, however, in nature everything proceeds from a cause, everything *actual* is also *necessary*, yet only so far as it is *at this time, in this place;* for only so far does determination by the law of causality extend. Let us leave, however, concrete nature and pass over to abstract thinking; then we can present to ourselves in reflection all the natural laws which are known to us partly *a priori*, partly only *a posteriori*, and this abstract idea contains all that is in nature at *any* time, in

any place, but with abstraction from every definite time and place; and just in this way, through such reflection, we have entered the wide kingdom of *the possible*. But what finds no place even here is the *impossible*. It is clear that possibility and impossibility exist only for reflection, for abstract knowledge of the reason, not for knowledge of perception; although it is the pure forms of perception which supply the reason with the determination of the possible and impossible. According as the laws of nature, from which we start in the thought of the possible and impossible, are known *a priori* or *a posteriori*, is the possibility or impossibility metaphysical or physical.

From this exposition, which requires no proof because it rests directly upon the knowledge of the principle of sufficient reason and upon the development of the conceptions of the necessary, the actual, and the possible, it is sufficiently evident how entirely groundless is Kant's assumption of three special functions of the understanding for these three conceptions, and that here again he has allowed himself to be disturbed by no reflection in the carrying out of his architectonic symmetry.

To this, however, we have to add the other great mistake, that, certainly according to the procedure of earlier philosophy, he has confounded the conceptions of necessity and contingency with each other. That earlier philosophy has applied abstraction to the following mistaken use. It was clear that that of which the reason is given inevitably follows, *i.e.*, cannot not be, and thus necessarily is. But that philosophy held to this last determination alone, and said that is necessary which cannot be otherwise, or the opposite of which is impossible. It left, however, the ground and root of such necessity out of account, overlooked the relativity of all necessity which follows from it, and thereby made the quite unthinkable fiction of an *absolute necessity*, *i.e.*, of something the existence of which would be as inevitable as the consequent of a reason, but which yet was not the consequent of a reason, and therefore depended upon nothing; an addition which is an absurd *petitio*, for it conflicts with the principle of sufficient reason. Now, starting from this fiction, it explained, in diametrical opposition to the truth, all that is established by a reason as contingent, because it looked at the relative nature of its necessity and compared this with that entirely imaginary *absolute* necessity, which is self-contradictory in its conception.[5] Now Kant adheres to this fundamentally perverse definition of the contingent and gives it as explanation. (Critique of Pure Reason, V. p. 289-291, 243. V. 301, 419. V. 447, 486, 488.) He falls indeed

into the most evident contradiction with himself upon this point, for on p. 301 he says: “Everything contingent has a cause,” and adds, “That is contingent which might possibly not be.” But whatever has a cause cannot possibly not be: thus it is necessary. For the rest, the source of the whole of this false explanation of the necessary and the contingent is to be found in Aristotle in “*De Generatione et Corruptione*,” lib. ii. c. 9 et 11, where the necessary is explained as that which cannot possibly not be: there stands in opposition to it that which cannot possibly be, and between these two lies that which can both be and not be, — thus that which comes into being and passes away, and this would then be the contingent. In accordance with what has been said above, it is clear that this explanation, like so many of Aristotle’s, has resulted from sticking to abstract conceptions without going back to the concrete and perceptible, in which, however, the source of all abstract conceptions lies, and by which therefore they must always be controlled. “Something which cannot possibly not be” can certainly be thought in the abstract, but if we go with it to the concrete, the real, the perceptible, we find nothing to support the thought, even as possible, — as even merely the asserted consequent of a given reason, whose necessity is yet relative and conditioned.

I take this opportunity of adding a few further remarks on these conceptions of modality. Since all necessity rests upon the principle of sufficient reason, and is on this account relative, all *apodictic* judgments are originally, and according to their ultimate significance, *hypothetical*. They become *categorical* only through the addition of an *assertatory* minor, thus in the conclusion. If this minor is still undecided, and this indecision is expressed, this gives the problematical judgment.

What in general (as a rule) is apodictic (a law of nature), is in reference to a particular case only problematical, because the condition must actually appear which brings the case under the rule. And conversely, what in the particular as such is necessary (apodictic) (every particular change necessary through the cause), is again in general, and predicated universally, only problematical; because the causes which appear only concern the particular case, and the apodictic, always hypothetical judgment, always expresses merely the general law, not the particular case directly. All this has its ground in the fact that possibility exists only in the province of reflection and for the reason; the actual, in the province of perception and for the understanding; the necessary, for both. Indeed, the

distinction between necessary, actual, and possible really exists only in the abstract and according to the conception; in the real world, on the other hand, all three fall into one. For all that happens, happens *necessarily*, because it happens from causes; but these themselves have again causes, so that the whole of the events of the world, great and small, are a strict concatenation of necessary occurrences. Accordingly everything actual is also necessary, and in the real world there is no difference between actuality and necessity, and in the same way no difference between actuality and possibility; for what has not happened, *i.e.*, has not become actual, was also not possible, because the causes without which it could never appear have not themselves appeared, nor could appear, in the great concatenation of causes; thus it was an impossibility. Every event is therefore either necessary or impossible. All this holds good only of the empirically real world, *i.e.*, the complex of individual things, thus of the whole particular as such. If, on the other hand, we consider things generally, comprehending them *in abstracto*, necessity, actuality, and possibility are again separated; we then know everything which is in accordance with the *a priori* laws which belong to our intellect as possible in general; that which corresponds to the empirical laws of nature as possible in this world, even if it has never become actual; thus we distinguish clearly the possible from the actual. The actual is in itself always also necessary, but is only comprehended as such by him who knows its cause; regarded apart from this, it is and is called contingent. This consideration also gives us the key to that *contentio* περι δυνατων between the Megaric Diodorus and Chrysippus the Stoic which Cicero refers to in his book *De Fato*. Diodorus says: "Only what becomes actual was possible, and all that is actual is also necessary." Chrysippus on the other hand says: "Much that is possible never becomes actual; for only the necessary becomes actual." We may explain this thus: Actuality is the conclusion of a syllogism to which possibility gives the premises. But for this is required not only the major but also the minor; only the two give complete possibility. The major gives a merely theoretical, general possibility *in abstracto*, but this of itself does not make anything possible, *i.e.*, capable of becoming actual. For this the minor also is needed, which gives the possibility for the particular case, because it brings it under the rule, and thereby it becomes at once actual. For example:

Maj. All houses (consequently also my house) can be destroyed by fire.

Min. My house is on fire.

Concl. My house is being destroyed by fire.

For every general proposition, thus every major, always determines things with reference to actuality only under a presupposition, therefore hypothetically; for example, the capability of being burnt down has as a presupposition the catching fire. This presupposition is produced in the minor. The major always loads the cannon, but only if the minor brings the match does the shot, *i.e.*, the conclusion, follow. This holds good throughout of the relation of possibility to actuality. Since now the conclusion, which is the assertion of actuality, always follows *necessarily*, it is evident from this that all that is actual is also necessary, which can also be seen from the fact that necessity only means being the consequent of a given reason: this is in the case of the actual a cause: thus everything actual is necessary. Accordingly, we see here the conceptions of the possible, the actual, and the necessary unite, and not merely the last presuppose the first, but also the converse. What keeps them apart is the limitation of our intellect through the form of time; for time is the mediator between possibility and actuality. The necessity of the particular event may be fully seen from the knowledge of all its causes; but the concurrence of the whole of these different and independent causes seems to us *contingent*; indeed their independence of each other is just the conception of contingency. Since, however, each of them was the necessary effect of *its* causes, the chain of which has no beginning, it is evident that contingency is merely a subjective phenomenon, arising from the limitation of the horizon of our understanding, and just as subjective as the optical horizon at which the heavens touch the earth.

Since necessity is the same thing as following from given grounds, it must appear in a special way in the case of every form of the principle of sufficient reason, and also have its opposite in the possibility and impossibility which always arises only through the application of the abstract reflection of the reason to the object. Therefore the four kinds of necessity mentioned above stand opposed to as many kinds of impossibility, physical, logical, mathematical and practical. It may further be remarked that if one remains entirely within the province of abstract concepts, possibility is always connected with the more general, and necessity with the more limited concept; for example, “An animal *may* be a bird, a fish, an amphibious creature, &c.” “A nightingale *must* be a bird, a bird *must* be an animal, an animal *must* be an organism, an organism *must* be a body.” This

is because logical necessity, the expression of which is the syllogism, proceeds from the general to the particular, and never conversely. In the concrete world of nature (ideas of the first class), on the contrary, everything is really necessary through the law of causality; only added reflection can conceive it as also contingent, comparing it with that which is not its cause, and also as merely and purely actual, by disregarding all causal connection. Only in this class of ideas does the conception of the *actual* properly occur, as is also shown by the derivation of the word from the conception of causality. In the third class of ideas, that of pure mathematical perception or intuition, if we confine ourselves strictly to it, there is only necessity. Possibility occurs here also only through relation to the concepts of reflection: for example, "A triangle *may* be right-angled, obtuse-angled, or equiangular; its three angles *must* be equal to two right-angles." Thus here we only arrive at the possible through the transition from the perceptible to the abstract.

After this exposition, which presupposes the recollection of what was said both in the essay on the principle of sufficient reason and in the first book of the present work, there will, it is hoped, be no further doubt as to the true and very heterogeneous source of those forms which the table of judgments lays before us, nor as to the inadmissibility and utter groundlessness of the assumption of twelve special functions of the understanding for the explanation of them. The latter point is also supported by a number of special circumstances very easily noted. Thus, for example, it requires great love of symmetry and much trust in a clue derived from it, to lead one to assume that an affirmative, a categorical, and an assertatory judgment are three such different things that they justify the assumption of an entirely special function of the understanding for each of them.

Kant himself betrays his consciousness of the untenable nature of his doctrine of the categories by the fact that in the third chapter of the Analytic of Principles (*phænomena et noumena*) several long passages of the first edition (p. 241, 242, 244-246, 248-253) are omitted in the second — passages which displayed the weakness of that doctrine too openly. So, for example, he says there (p. 241) that he has not defined the individual categories, because he could not define them even if he had wished to do so, inasmuch as they were susceptible of no definition. In saying this he forgot that at p. 82 of the same first edition he had said: "I purposely dispense with the definition of the categories although I may be in possession of it." This

then was, *sit venia verbo*, wind. But this last passage he has allowed to stand. And so all those passages wisely omitted afterwards betray the fact that nothing distinct can be thought in connection with the categories, and this whole doctrine stands upon a weak foundation.

This table of the categories is now made the guiding clue according to which every metaphysical, and indeed every scientific inquiry is to be conducted (Prolegomena, § 39). And, in fact, it is not only the foundation of the whole Kantian philosophy and the type according to which its symmetry is everywhere carried out, as I have already shown above, but it has also really become the procrustean bed into which Kant forces every possible inquiry, by means of a violence which I shall now consider somewhat more closely. But with such an opportunity what must not the *imitatores servum pecus* have done! We have seen. That violence then is applied in this way. The meaning of the expressions denoted by the titles, forms of judgment and categories, is entirely set aside and forgotten, and the expressions alone are retained. These have their source partly in Aristotle's *Analyt. priora*, i. 23 (περι ποιοτητος και ποσοτητος των του συλλογισμου ὀρων: *de qualitate et quantitate terminorum syllogismi*), but are arbitrarily chosen; for the extent of the concepts might certainly have been otherwise expressed than through the word *quantity*, though this word is more suited to its object than the rest of the titles of the categories. Even the word *quality* has obviously been chosen on account of the custom of opposing quality to quantity; for the name quality is certainly taken arbitrarily enough for affirmation and negation. But now in every inquiry instituted by Kant, every quantity in time and space, and every possible quality of things, physical, moral, &c., is brought by him under those category titles, although between these things and those titles of the forms of judgment and of thought there is absolutely nothing in common except the accidental and arbitrary nomenclature. It is needful to keep in mind all the respect which in other regards is due to Kant to enable one to refrain from expressing in hard terms one's repugnance to this procedure. The nearest example is afforded us at once by the pure physiological table of the general principles of natural science. What in all the world has the quantity of judgments to do with the fact that every perception has an extensive magnitude? What has the quality of judgments to do with the fact that every sensation has a degree? The former rests rather on the fact that space is the form of our external perception, and the latter is nothing more than an empirical, and, moreover, entirely subjective feeling,

drawn merely from the consideration of the nature of our organs of sense. Further, in the table which gives the basis of rational psychology (Critique of Pure Reason, p. 344; V. 402), the *simplicity* of the soul is cited under quality; but this is just a quantitative property, and has absolutely no relation to the affirmation or negation in the judgment. But quantity had to be completed by the *unity* of the soul, which is, however, already included in its simplicity. Then modality is forced in in an absurd way; the soul stands in connection with *possible* objects; but connection belongs to relation, only this is already taken possession of by substance. Then the four cosmological Ideas, which are the material of the antinomies, are referred to the titles of the categories; but of this we shall speak more fully further on, when we come to the examination of these antinomies. Several, if possible, still more glaring examples are to be found in the table of the *Categories of Freedom!* in the "Critique of Practical Reason;" also in the first book of the "Critique of Judgment," which goes through the judgment of taste according to the four titles of the categories; and, finally, in the "Metaphysical First Principles of Natural Science," which are entirely adapted to the table of the categories, whereby the false that is mingled here and there with what is true and excellent in this important work is for the most part introduced. See, for example, at the end of the first chapter how the unity, the multiplicity, and the totality of the directions of lines are supposed to correspond to the categories, which are so named according to the quantity of judgments.

The principle of the *Permanence of Substance* is deduced from the category of subsistence and inherence. This, however, we know only from the form of the categorical judgment, *i.e.*, from the connection of two concepts as subject and predicate. With what violence then is that great metaphysical principle made dependent upon this simple, purely logical form! Yet this is only done *pro forma*, and for the sake of symmetry. The proof of this principle, which is given here, sets entirely aside its supposed origin in the understanding and in the category, and is based upon the pure intuition or perception of time. But this proof also is quite incorrect. It is false that in mere time there is *simultaneity* and *duration*; these ideas only arise from the union of *space* with time, as I have already shown in the essay on the principle of sufficient reason, § 18, and worked out more fully in § 4 of the present work. I must assume a knowledge of both these

expositions for the understanding of what follows. It is false that time *remains* the same through all change; on the contrary, it is just time itself that is fleeting; a permanent time is a contradiction. Kant's proof is untenable, strenuously as he has supported it with sophisms; indeed, he falls into the most palpable contradictions. Thus, after he has falsely set up co-existence as a mode of time (p. 177; V. 219), he says, quite rightly (p. 183; V. 226), "Co-existence is not a mode of time, for in time there are absolutely no parts together, but all in succession." In truth, space is quite as much implicated in co-existence as time. For if two things are co-existent and yet not one, they are different in respect of space; if two states of one thing are co-existent (*e.g.*, the glow and the heat of iron), then they are two contemporaneous effects of *one* thing, therefore presuppose matter, and matter presupposes space. Strictly speaking, co-existence is a negative determination, which merely signifies that two things or states are not different in respect of time; thus their difference is to be sought for elsewhere. But in any case, our knowledge of the permanence of substance, *i.e.*, of matter, must be based upon insight *a priori*; for it is raised above all doubt, and therefore cannot be drawn from experience. I deduce it from the fact that the principle of all becoming and passing away, the law of causality, of which we are conscious *a priori*, is essentially concerned only with the *changes*, *i.e.*, the successive *states* of matter, is thus limited to the form, and leaves the matter untouched, which therefore exists in our consciousness as the foundation of all things, which is not subject to becoming or passing away, which has therefore always been and will always continue to be. A deeper proof of the permanence of substance, drawn from the analysis of our perception of the empirical world in general, is to be found in the first book of this work, § 4, where it is shown that the nature of matter consists in the absolute *union of space and time*, a union which is only possible by means of the idea of causality, consequently only for the understanding, which is nothing but the subjective correlative of causality. Hence, also, matter is never known otherwise than as producing effects, *i.e.*, as through and through causality; to be and to act are with it one, which is indeed signified by the word *actuality*. Intimate union of space and time — causality, matter, actuality — are thus one, and the subjective correlative of this one is the understanding. Matter must bear in itself the conflicting properties of both factors from which it proceeds, and it is the idea of causality which abolishes what is contradictory in both, and

makes their co-existence conceivable by the understanding, through which and for which alone matter is, and whose whole faculty consists in the knowledge of cause and effect. Thus for the understanding there is united in matter the inconstant flux of time, appearing as change of the accidents, with the rigid immobility of space, which exhibits itself as the permanence of substance. For if the substance passed away like the accidents, the phenomenon would be torn away from space altogether, and would only belong to time; the world of experience would be destroyed by the abolition of matter, annihilation. Thus from the share which space has in matter, *i.e.*, in all phenomena of the actual — in that it is the opposite and counterpart of time, and therefore in itself and apart from the union with the latter knows absolutely no change — the principle of the permanence of substance, which recognises everything as *a priori* certain, had to be deduced and explained; but not from mere time, to which for this purpose and quite erroneously Kant has attributed *permanence*.

In the essay on the principle of sufficient reason, § 23, I have fully explained the incorrectness of the following proof of the *a priori* nature and of the necessity of the law of causality from the mere succession of events in time; I must, therefore, content myself here by referring to that passage.[6] This is precisely the case with the proof of reciprocity also, the concept of which I was obliged to explain above as invalid. What is necessary has also been said of modality, the working out of the principles of which now follows.

There are still a few points in the further course of the transcendental analytic which I should have to refute were it not that I am afraid of trying the patience of the reader; I therefore leave them to his own reflection. But ever anew in the "Critique of Pure Reason" we meet that principal and fundamental error of Kant's, which I have copiously denounced above, the complete failure to distinguish abstract, discursive knowledge from intuitive. It is this that throws a constant obscurity over Kant's whole theory of the faculty of knowledge, and never allows the reader to know what he is really speaking about at any time, so that instead of understanding, he always merely conjectures, for he alternately tries to understand what is said as referring to thought and to perception, and remains always in suspense. In the chapter "On the Division of all Objects into Phenomena and Noumena," Kant carries that incredible want of reflection as to the nature of the idea of perception and the abstract idea, as I

shall explain more fully immediately, so far as to make the monstrous assertion that without thought, that is, without abstract conceptions, there is no knowledge of an object; and that perception, because it is not thought, is also not knowledge, and, in general, is nothing but a mere affection of sensibility, mere sensation! Nay, more, that perception without conception is absolutely void; but conception without perception is yet always something (p. 253; V. 309). Now this is exactly the opposite of the truth; for concepts obtain all significance, all content, only from their relation to ideas of perception, from which they have been abstracted, derived, that is, constructed through the omission of all that is unessential: therefore if the foundation of perception is taken away from them, they are empty and void. Perceptions, on the contrary, have in themselves immediate and very great significance (in them, indeed, the thing in itself objectifies itself); they represent themselves, express themselves, have no mere borrowed content like concepts. For the principle of sufficient reason governs them only as the law of causality, and determines as such only their position in space and time; it does not, however, condition their content and their significance, as is the case with concepts, in which it appears as the principle of the ground of knowing. For the rest, it looks as if Kant really wished here to set about distinguishing the idea of perception and the abstract idea. He objects to Leibnitz and Locke that the former reduced everything to abstract ideas, and the latter everything to ideas of perception. But yet he arrives at no distinction; and although Locke and Leibnitz really committed these errors, Kant himself is burdened with a third error which includes them both — the error of having so mixed up knowledge of perception and abstract knowledge that a monstrous hybrid of the two resulted, a chimera of which no distinct idea is possible, and which therefore necessarily only confused and stupefied students, and set them at variance.

Certainly thought and perception are separated more in the chapter referred to "On the Division of all Objects into Phenomena and Noumena" than anywhere else, but the nature of this distinction is here a fundamentally false one. On p. 253; V. 309, it is said: "If I take away all thought (through the categories) from empirical knowledge, there remains absolutely no knowledge of an object, for through mere perception nothing at all is thought, and that this affection of sensibility is in me establishes really no relation of such ideas to any object." This sentence contains, in some degree, all the errors of Kant in a nutshell; for it brings out clearly that he

has falsely conceived the relation between sensation, perception, and thought, and accordingly identifies the perception, whose form he yet supposes to be space, and indeed space in all its three dimensions, with the mere subjective sensation in the organs of sense, but only allows the knowledge of an object to be given through thought, which is different from perception. I, on the contrary, say: Objects are first of all objects of perception, not of thought, and all knowledge of *objects* is originally and in itself perception. Perception, however, is by no means mere sensation, but the understanding is already active in it. The thought, which is added only in the case of men, not in the case of the brutes, is mere abstraction from perception, gives no fundamentally new knowledge, does not itself establish objects which were not before, but merely changes the form of the knowledge already won through perception, makes it abstract knowledge in concepts, whereby its concrete or perceptible character is lost, but, on the other hand, combination of it becomes possible, which immeasurably extends the range of its applicability. The material of our thought is, on the other hand, nothing else than our perceptions themselves, and not something which the perceptions did not contain, and which was added by the thought; therefore the material of everything that appears in our thought must be capable of verification in our perception, for otherwise it would be an empty thought. Although this material is variously manipulated and transformed by thought, it must yet be capable of being reduced to perception, and the thought traced back to this — just as a piece of gold can be reduced from all its solutions, oxides, sublimates, and combinations, and presented pure and undiminished. This could not happen if thought itself had added something, and, indeed, the principal thing, to the object.

The whole of the chapter on the Amphiboly, which follows this, is merely a criticism of the Leibnitzian philosophy, and as such is on the whole correct, though the form or pattern on which it is constructed is chosen merely for the sake of architectonic symmetry, which here also is the guiding clue. Thus, to carry out the analogy with the Aristotelian Organon, a transcendental Topic is set up, which consists in this, that every conception is to be considered from four points of view, in order to make out to which faculty of knowledge it belongs. But these four points of view are quite arbitrarily selected, and ten others might be added to them with just as much right; but their fourfold number corresponds to the titles of the categories, and therefore the chief doctrine of Leibnitz is divided among

them as best it may be. By this critique, also, to some extent, certain errors are stamped as natural to the reason, whereas they were merely false abstractions of Leibnitz's, who, rather than learn from his great philosophical contemporaries, Spinoza and Locke, preferred to serve up his own strange inventions. In the chapter on the Amphiboly of Reflection it is finally said that there may possibly be a kind of perception entirely different from ours, to which, however, our categories are applicable; therefore the objects of that supposed perception would be *noumena*, things which can only be *thought* by us; but since the perception which would give that thought meaning is wanting to us, and indeed is altogether quite problematical, the object of that thought would also merely be a wholly indefinite possibility. I have shown above by quotations that Kant, in utter contradiction with himself, sets up the categories now as the condition of knowledge of perception, now as the function of merely abstract thought. Here they appear exclusively in the latter sense, and it seems quite as if he wished to attribute them merely to discursive thought. But if this is really his opinion, then necessarily at the beginning of the Transcendental Logic, before specifying the different functions of thought at such length, he was necessarily bound to characterise thought in general, and consequently to distinguish it from perception; he ought to have shown what knowledge is given by mere perception, and what that is new is added by thought. Then we would have known what he was really speaking about; or rather, he would then have spoken quite differently, first of perception, and then of thought; instead of which, as it is, he is always dealing with something between the two, which is a mere delusion. There would not then be that great gap between the transcendental Æsthetic and the transcendental Logic, where, after the exposition of the mere form of perception, he simply dismisses its content, all that is empirically apprehended, with the phrase "It is given," and does not ask how it came about, *whether with or without understanding*; but, with one spring, passes over to abstract thought; and not even to thought in general, but at once to certain forms of thought, and does not say a word about what thought is, what the concept is, what is the relation of abstract and discursive to concrete and intuitive, what is the difference between the knowledge of men and that of brutes, and what is reason.

Yet it was just this distinction between abstract knowledge and knowledge of perception, entirely overlooked by Kant, which the ancients

denoted by φαινομενα and νοουμενα,[7] and whose opposition and incommensurability occupied them so much in the philosophemes of the Eleatics, in Plato's doctrine of Ideas, in the dialectic of the Megarics, and later the Scholastics in the controversy between Nominalism and Realism, the seed of which, so late in developing, was already contained in the opposite mental tendencies of Plato and Aristotle. But Kant, who, in an inexcusable manner, entirely neglected the thing to denote which the words φαινομενα and νοουμενα had already been taken, took possession of the words, as if they were still unappropriated, in order to denote by them his thing in itself and his phenomenon.

Since I have been obliged to reject Kant's doctrine of the categories, just as he rejected that of Aristotle, I wish here to indicate as a suggestion a third way of reaching what is aimed at. What both Kant and Aristotle sought for under the name of the categories were the most general conceptions under which all things, however different, must be subsumed, and through which therefore everything that exists would ultimately be thought. Just on this account Kant conceived them as the *forms* of all thought.

Grammar is related to logic as clothes to the body. Should not, therefore, these primary conceptions, the ground-bass of the reason, which is the foundation of all special thought, without whose application, therefore, no thought can take place, ultimately lie in those conceptions which just on account of their exceeding generality (transcendentalism) have their expression not in single words, but in whole classes of words, because one of them is thought along with every word whatever it may be, whose designation would therefore have to be looked for, not in the lexicon but in the grammar? In fact, should they not be those distinctions of conceptions on account of which the word which expresses them is either a substantive or an adjective, a verb or an adverb, a pronoun, a preposition, or some other particle — in short, the parts of speech? For undoubtedly these denote the forms which all thought primarily assumes, and in which it directly moves; accordingly they are the essential forms of speech, the fundamental constituent elements of every language, so that we cannot imagine any language which would not consist of at least substantives, adjectives, and verbs. These fundamental forms would then have subordinated to them those forms of thought which are expressed through their inflections, that is, through declension and conjugation, and it is unessential to the chief

concern whether in denoting them we call in the assistance of the article and the pronoun. We will examine the thing, however, somewhat more closely, and ask the question anew: What are the forms of thought?

(1.) Thought consists throughout of judging; judgments are the threads of its whole web, for without making use of a verb our thought does not move, and as often as we use a verb we judge.

(2.) Every judgment consists in the recognition of the relation between subject and predicate, which it separates or unites with various restrictions. It unites them from the recognition of the actual identity of the two, which can only happen in the case of synonyms; then in the recognition that the one is always thought along with the other, though the converse does not hold — in the universal affirmative proposition; up to the recognition that the one is sometimes thought along with the other, in the particular affirmative proposition. The negative propositions take the opposite course. Accordingly in every judgment the subject, the predicate, and the copula, the latter affirmative or negative, must be to be found; even although each of these is not denoted by a word of its own, as is however generally the case. The predicate and the copula are often denoted by *one* word, as "Caius ages;" sometimes one word denotes all three, as *concurritur*, *i.e.*, "the armies engage." From this it is evident that the forms of thought are not to be sought for precisely and directly in words, nor even in the parts of speech, for even in the same language the same judgment may be expressed in different words, and indeed in different parts of speech, yet the thought remains the same, and consequently also its form; for the thought could not be the same if the form of thought itself were different. But with the same thought and the same form of thought the form of words may very well be different, for it is merely the outward clothing of the thought, which, on the other hand, is inseparable from *its* form. Thus grammar only explains the clothing of the forms of thought. The parts of speech can therefore be deduced from the original forms of thought themselves which are independent of all language; their work is to express these forms of thought in all their modifications. They are the instrument and the clothing of the forms of thought, and must be accurately adapted to the structure of the latter, so that it may be recognised in them.

(3.) These real, unalterable, original forms of thought are certainly *those of Kant's logical table of judgments*; only that in this table are to be found

blind windows for the sake of symmetry and the table of the categories; these must all be omitted, and also a false arrangement. Thus: —

(*a.*) *Quality*: affirmation and negation, *i.e.*, combination and separation of concepts: two forms. It depends on the copula.

(*b.*) *Quantity*: the subject-concept is taken either in whole or in part: totality or multiplicity. To the first belong also individual subjects: Socrates means "all Socrateses." Thus two forms. It depends on the subject.

(*c.*) *Modality*: has really three forms. It determines the quality as necessary, actual, or contingent. It consequently depends also on the copula.

These three forms of thought spring from the laws of thought of contradiction and identity. But from the principle of sufficient reason and the law of excluded middle springs —

(*d.*) *Relation.* It only appears if we judge concerning completed judgments, and can only consist in this, that it either asserts the dependence of one judgment upon another (also in the plurality of both), and therefore combines them in the *hypothetical* proposition; or else asserts that judgments exclude each other, and therefore separates them in the *disjunctive* proposition. It depends on the copula, which here separates or combines the completed judgments.

The *parts of speech* and grammatical forms are ways of expressing the three constituent parts of the judgment, the subject, the predicate, and the copula, and also of the possible relations of these; thus of the forms of thought just enumerated, and the fuller determinations and modifications of these. Substantive, adjective, and verb are therefore essential fundamental constituent elements of language in general; therefore they must be found in all languages. Yet it is possible to conceive a language in which adjective and verb would always be fused together, as is sometimes the case in all languages. Provisionally it may be said, for the expression of the *subject* are intended the substantive, the article, and the pronoun; for the expression of the *predicate*, the adjective, the adverb, and the preposition; for the expression of the *copula*, the verb, which, however, with the exception of the verb to be, also contains the predicate. It is the task of the philosophy of grammar to teach the precise mechanism of the expression of the forms of thought, as it is the task of logic to teach the operations with the forms of thought themselves.

Note. — As a warning against a false path and to illustrate the above, I mention S. Stern's "*Vorläufige Grundlage zur Sprachphilosophie*," 1835,

which is an utterly abortive attempt to construct the categories out of the grammatical forms. He has entirely confused thought with perception, and therefore, instead of the categories of thought, he has tried to deduce the supposed categories of perception from the grammatical forms, and consequently has placed the grammatical forms in direct relation to perception. He is involved in the great error that *language* is immediately related to *perception*, instead of being directly related only to thought as such, thus to the *abstract concepts*, and only by means of these to perception, to which they, however, have a relation which introduces an entire change of the form. What exists in perception, thus also the relations which proceed from time and space, certainly becomes an object of thought; thus there must also be forms of speech to express it, yet always merely in the abstract, as concepts. Concepts are always the primary material of thought, and the forms of logic are always related to these, never *directly* to perception. Perception always determines only the material, never the formal truth of the proposition, for the formal truth is determined according to the logical rules alone.

I return to the Kantian philosophy, and come now to the *Transcendental Dialectic*. Kant opens it with the explanation of *reason*, the faculty which is to play the principal part in it, for hitherto only sensibility and understanding were on the scene. When considering his different explanations of reason, I have already spoken above of the explanation he gives here that "it is the faculty of principles." It is now taught here that all the *a priori* knowledge hitherto considered, which makes pure mathematics and pure natural science possible, affords only *rules*, and no *principles*; because it proceeds from perceptions and forms of knowledge, and not from mere conceptions, which is demanded if it is to be called a principle. Such a principle must accordingly be knowledge *from pure conceptions* and yet *synthetical*. But this is absolutely impossible. From pure conceptions nothing but *analytical* propositions can ever proceed. If conceptions are to be synthetically and yet *a priori* combined, this combination must necessarily be accomplished by some third thing, through a pure perception of the formal possibility of experience, just as synthetic judgments *a posteriori* are brought about through empirical perception; consequently a synthetic proposition *a priori* can never proceed from pure conceptions. In

general, however, we are *a priori* conscious of nothing more than the principle of sufficient reason in its different forms, and therefore no other synthetic judgments *a priori* are possible than those which proceed from that which receives its content from that principle.

However, Kant finally comes forward with a pretended principle of the reason answering to his demand, yet only with this *one*, from which others afterwards follow as corollaries. It is the principle which Chr. Wolf set up and explained in his "*Cosmologia*," sect. i. c. 2, § 93, and in his "*Ontologia*," § 178. As now above, under the title of the Amphiboly, mere Leibnitzian philosophemes were taken for natural and necessary aberrations of the reason, and were criticised as such, so here precisely the same thing happens with the philosophemes of Wolf. Kant still presents this principle of the reason in an obscure light, through indistinctness, indefiniteness, and breaking of it up (p. 307; V. 361, and 322; V. 379). Clearly expressed, however, it is as follows: "If the conditioned is given, the totality of its conditions must also be given, and therefore also the *unconditioned*, through which alone that totality becomes complete." We become most vividly aware of the apparent truth of this proposition if we imagine the conditions and the conditioned as the links of a suspended chain, the upper end of which, however, is not visible, so that it might extend *ad infinitum*; since, however, the chain does not fall, but hangs, there must be above *one* link which is the first, and in some way is fixed. Or, more briefly: the reason desires to have a point of attachment for the causal chain which reaches back to infinity; it would be convenient for it. But we will examine the proposition, not in figures, but in itself. Synthetic it certainly is; for, analytically, nothing more follows from the conception of the conditioned than that of the condition. It has not, however, *a priori* truth, nor even *a posteriori*, but it surreptitiously obtains its appearance of truth in a very subtle way, which I must now point out. Immediately, and *a priori*, we have the knowledge which the principle of sufficient reason in its four forms expresses. From this immediate knowledge all abstract expressions of the principle of sufficient reason are derived, and they are thus indirect; still more, however, is this the case with inferences or corollaries from them. I have already explained above how *abstract* knowledge often unites a variety of *intuitive* cognitions in *one* form or *one* concept in such a way that they can no longer be distinguished; therefore abstract knowledge stands to intuitive knowledge as the shadow to the real objects, the great multiplicity

of which it presents through one outline comprehending them all. Now the pretended principle of the reason makes use of this shadow. In order to deduce from the principle of sufficient reason the unconditioned, which directly contradicts it, it prudently abandons the immediate concrete knowledge of the content of the principle of sufficient reason in its particular forms, and only makes use of abstract concepts which are derived from it, and have value and significance only through it, in order to smuggle its unconditioned somehow or other into the wide sphere of those concepts. Its procedure becomes most distinct when clothed in dialectical form; for example, thus: "If the conditioned exists, its condition must also be given, and indeed all given, thus completely, thus the totality of its conditions; consequently, if they constitute a series, the whole series, consequently also its first beginning, thus the unconditioned." Here it is false that the conditions of a conditioned can constitute a *series*. Rather must the totality of the conditions of everything conditioned be contained in its *nearest* ground or reason from which it directly proceeds, and which is only thus a *sufficient* ground or reason. For example, the different determinations of the state which is the cause, all of which must be present together before the effect can take place. But the series, for example, the chain of causes, arises merely from the fact that we regard what immediately before was the condition as now a conditioned; but then at once the whole operation begins again from the beginning, and the principle of sufficient reason appears anew with its claim. But there can never be for a conditioned a properly successive *series* of conditions, which exist merely as such, and on account of that which is at last conditioned; it is always an alternating series of conditioneds and conditions; as each link is laid aside the chain is broken, and the claim of the principle of sufficient reason entirely satisfied, it arises anew because the condition becomes the conditioned. Thus the principle of *sufficient* reason always demands only the completeness of the *immediate or next condition*, never the completeness of a *series*. But just this conception of the completeness of the condition leaves it undetermined whether this completeness should be simultaneous or successive; and since the latter is chosen, the demand now arises for a complete series of conditions following each other. Only through an arbitrary abstraction is a series of causes and effects regarded as a series of causes alone, which exists merely on account of the last effect, and is therefore demanded as its *sufficient* reason. From closer and more

intelligent consideration, and by rising from the indefinite generality of abstraction to the particular definite reality, it appears, on the contrary, that the demand for a *sufficient* reason extends only to the completeness of the determinations of the *immediate* cause, not to the completeness of a series. The demand of the principle of sufficient reason is completely extinguished in each sufficient reason given. It arises, however, immediately anew, because this reason is again regarded as a consequent; but it never demands directly a series of reasons. If, on the other hand, instead of going to the thing itself, we confine ourselves to the abstract concepts, these distinctions vanish. Then a chain of alternating causes and effects, or of alternating logical reasons and consequents, is given out as simply a chain of causes of the last effect, or reasons of the last consequent, and the *completeness of the conditions*, through which alone a reason becomes *sufficient*, appears as the completeness of that assumed *series* of reasons alone, which only exist on account of the last consequent. There then appears the abstract principle of the reason very boldly with its demand for the unconditioned. But, in order to recognise the invalidity of this claim, there is no need of a critique of reason by means of antinomies and their solution, but only of a critique of reason understood in my sense, an examination of the relation of abstract knowledge to direct intuitive knowledge, by means of ascending from the indefinite generality of the former to the fixed definiteness of the latter. From such a critique, then, it here appears that the nature of the reason by no means consists in the demand for an unconditioned; for, whenever it proceeds with full deliberation, it must itself find that an unconditioned is an absurdity. The reason as a faculty of knowledge can always have to do only with objects; but every object for the subject is necessarily and irrevocably subordinated to the principle of sufficient reason, both *a parte ante* and *a parte post*. The validity of the principle of sufficient reason is so involved in the form of consciousness that we absolutely cannot imagine anything objective of which no *why* could further be demanded; thus we cannot imagine an absolute absolute, like a blind wall in front of us. That his convenience should lead this or that person to stop at some point, and assume such an absolute at pleasure, is of no avail against that incontestable certainty *a priori*, even if he should put on an air of great importance in doing so. In fact, the whole talk about the absolute, almost the sole theme of philosophies since Kant, is nothing but the cosmological proof *incognito*. This proof, in consequence of the case brought against it by Kant, deprived

of all right and declared outlawed, dare no longer show itself in its true form, and therefore appears in all kinds of disguises — now in distinguished form, concealed under intellectual intuition or pure thought; now as a suspicious vagabond, half begging, half demanding what it wants in more unpretending philosophemes. If an absolute must absolutely be had, then I will give one which is far better fitted to meet all the demands which are made on such a thing than these visionary phantoms; it is matter. It has no beginning, and it is imperishable; thus it is really independent, and *quod per se est et per se concipitur*; from its womb all proceeds, and to it all returns; what more can be desired of an absolute? But to those with whom no critique of reason has succeeded, we should rather say —

“Are not ye like unto women, who ever
Return to the point from which they set out,
Though reason should have been talked by the hour?”

That the return to an unconditioned cause, to a first beginning, by no means lies in the nature of reason, is, moreover, practically proved by the fact that the primitive religions of our race, which even yet have the greatest number of followers upon earth, Brahmanism and Buddhaism, neither know nor admit such assumptions, but carry the series of phenomena conditioning each other into infinity. Upon this point, I refer to the note appended to the criticism of the first antinomy, which occurs further on; and the reader may also see Upham’s “Doctrine of Buddhaism” (p. 9), and in general all genuine accounts of the religions of Asia. Judaism and reason ought not to be identified.

Kant, who by no means desires to maintain his pretended principle of reason as objectively valid, but merely as subjectively necessary, deduces it even as such only by means of a shallow sophism, p. 307; V. 364. He says that because we seek to subsume every truth known to us under a more general truth, as far as this process can be carried, this is nothing else than the pursuit of the unconditioned, which we already presuppose. But, in truth, in this endeavour we do nothing more than apply reason, and intentionally make use of it to simplify our knowledge by enabling us to survey it — reason, which is that faculty of abstract, general knowledge that distinguishes the reflective, thinking man, endowed with speech, from the brute, which is the slave of the present. For the use of reason just consists in this, that we know the particular through the universal, the case through the rule, the rule through the more general rule; thus that we seek the most

general points of view. Through such survey or general view our knowledge is so facilitated and perfected that from it arises the great difference between the life of the brutes and that of men, and again between the life of educated and that of uneducated men. Now, certainly the series of *grounds of knowledge*, which exist only in the sphere of the abstract, thus of reason, always finds an end in what is indemonstrable, *i.e.*, in an idea which is not further conditioned according to this form of the principle of sufficient reason, thus in the *a priori* or *a posteriori* directly perceptible ground of the first proposition of the train of reasoning. I have already shown in the essay on the principle of sufficient reason, § 50, that here the series of grounds of knowledge really passes over into grounds of becoming or of being. But one can only desire to make this circumstance hold good as a proof of an unconditioned according to the law of causality, or even of the mere demand for such an unconditioned, if one has not yet distinguished the forms of the principle of sufficient reason at all, but, holding to the abstract expression, has confounded them all. Kant, however, seeks to establish that confusion, through a mere play upon words, with *Universalitas* and *Universitas*, p. 322; V. 379. Thus it is fundamentally false that our search for higher grounds of knowledge, more general truths, springs from the presupposition of an object unconditioned in its being, or has anything whatever in common with this. Moreover, how should it be essential to the reason to presuppose something which it must know to be an absurdity as soon as it reflects? The source of that conception of the unconditioned is rather to be found only in the indolence of the individual who wishes by means of it to get rid of all further questions, whether his own or of others, though entirely without justification.

Now Kant himself denies objective validity to this pretended principle of reason; he gives it, however, as a necessary subjective assumption, and thus introduces an irremediable split into our knowledge, which he soon allows to appear more clearly. With this purpose he unfolds that principle of reason further, p. 322; V. 379, in accordance with the method of architectonic symmetry of which he is so fond. From the three categories of relation spring three kinds of syllogisms, each of which gives the clue for the discovery of a special unconditioned, of which again there are three: the soul, the world (as an object in itself and absolute totality), and God. Now here we must at once note a great contradiction, of which Kant, however, takes no notice, because it would be very dangerous to the symmetry. Two

of these unconditioneds are themselves conditioned by the third, the soul and the world by God, who is the cause of their existence. Thus the two former have by no means the predicate of unconditionedness in common with the latter, though this is really the point here, but only that of inferred being according to the principles of experience, beyond the sphere of the possibility of experience.

Setting this aside, we recognise in the three unconditioneds, to which, according to Kant, reason, following its essential laws, must come, the three principal subjects round which the whole of philosophy under the influence of Christianity, from the Scholastics down to Christian Wolf, has turned. Accessible and familiar as these conceptions have become through all these philosophers, and now also through the philosophers of pure reason, this by no means shows that, without revelation, they would necessarily have proceeded from the development of all reason as a production peculiar to its very nature. In order to prove this it would be necessary to call in the aid of historical criticism, and to examine whether the ancient and non-European nations, especially the peoples of Hindostan and many of the oldest Greek philosophers, really attained to those conceptions, or whether it is only we who, by quite falsely translating the Brahma of the Hindus and the Tien of the Chinese as "God," good-naturedly attribute such conceptions to them, just as the Greeks recognised their gods everywhere; whether it is not rather the case that theism proper is only to be found in the religion of the Jews, and in the two religions which have proceeded from it, whose followers just on this account comprise the adherents of all other religions on earth under the name of heathen, which, by the way, is a most absurd and crude expression, and ought to be banished at least from the writings of the learned, because it identifies and jumbles together Brahmanists, Buddhists, Egyptians, Greeks, Romans, Germans, Gauls, Iroquois, Patagonians, Caribbeans, Otaheiteans, Australians, and many others. Such an expression is all very well for priests, but in the learned world it must at once be shown the door: it can go to England and take up its abode at Oxford. It is a thoroughly established fact that Buddhism, the religion which numbers more followers than any other on earth, contains absolutely no theism, indeed rejects it. As regards Plato, it is my opinion that he owes to the Jews the theism with which he is periodically seized. On this account Numenius (according to Clem. Alex., *Strom.*, i. c. 22, Euseb. *præp. evang.*, xiii. 12, and Suidas under Numenius) called him the *Moses græcisans*: Τι γαρ εστι

Πλατων, η Μωσης αττικιζων; and he accuses him of having stolen (αποσυλησας) his doctrine of God and the creation from the Mosaical writings. Clemens often repeats that Plato knew and made use of Moses, *e.g.*, *Strom.*, i. 25. — v. c. 14, § 90, &c., &c.; *Pædagog.*, ii. 10, and iii. 11; also in the *Cohortatio ad gentes*, c. 6, where, after he has bitterly censured and derided the whole of the Greek philosophers in the preceding chapter because they were not Jews, he bestows on Plato nothing but praise, and breaks out into pure exultation that as Plato had learnt his geometry from the Egyptians, his astronomy from the Babylonians, magic from the Thracians, and much also from the Assyrians, so he had learnt his theism from the Jews: Οιδα σου τους διδασκαλους, καν αποκρυπτειν εθελῃς, ... δοξαν την του θεου παρʹ αυτων ωφελησει των Εβραιων (*Tuos magistros novi, licet eos celare velis, ... illa de Deo sententia suppeditata tibi est ab Hebræis*). A pathetic scene of recognition. But I see a remarkable confirmation of the matter in what follows. According to Plutarch (*in Mario*), and, better, according to Lactantius (i. 3, 19), Plato thanked Nature that he had been born a human being and not a brute, a man and not a woman, a Greek and not a barbarian. Now in Isaac Euchel's "Prayers of the Jews," from the Hebrew, second edition, 1799, p. 7, there is a morning prayer in which God is thanked and praised that the worshipper was born a Jew and not a heathen, a free man and not a slave, a man and not a woman. Such an historical investigation would have spared Kant an unfortunate necessity in which he now becomes involved, in that he makes these three conceptions spring necessarily from the nature of reason, and yet explains that they are untenable and unverifiable by the reason, and thus makes the reason itself a sophisticator; for he says, p. 339; V. 397: "There are sophistications, not of man, but of pure reason itself, from which even the wisest cannot free himself, and although after much trouble he may be able to avoid error, yet he never can escape from the illusion which unceasingly torments and mocks him." Therefore these Kantian "Ideas of the Reason" might be compared to the focus in which the converging reflected rays from a concave mirror meet several inches before its surface, in consequence of which, by an inevitable process of the understanding, an object presents itself to us there which is a thing without reality.

But the name "Idea" is very unfortunately chosen for these pretended necessary productions of the pure theoretical reason, and violently appropriated from Plato, who used it to denote the eternal forms which,

multiplied through space and time, become partially visible in the innumerable individual fleeting things. Plato's "Ideas" are accordingly throughout perceptible, as indeed the word which he chose so definitely signifies, for it could only be adequately translated by means of perceptible or visible things; and Kant has appropriated it to denote that which lies so far from all possibility of perception that even abstract thought can only half attain to it. The word "Idea," which Plato first introduced, has, moreover, since then, through two-and-twenty centuries, always retained the significance in which he used it; for not only all ancient philosophers, but also all the Scholastics, and indeed the Church Fathers and the theologians of the Middle Ages, used it only in that Platonic sense, the sense of the Latin word *exemplar*, as Suarez expressly mentions in his twenty-fifth Disputation, sect. 1. That Englishmen and Frenchmen were later induced by the poverty of their languages to misuse this word is bad enough, but not of importance. Kant's misuse of the word idea, by the substitution of a new significance introduced by means of the slender clue of not being object of experience, which it has in common with Plato's ideas, but also in common with every possible chimera, is thus altogether unjustifiable. Now, since the misuse of a few years is not to be considered against the authority of many centuries, I have always used the word in its old, original, Platonic significance.

The refutation of *rational psychology* is much fuller and more thorough in the first edition of the "Critique of Pure Reason" than in the second and following editions, and therefore upon this point we must make use of the first edition exclusively. This refutation has as a whole very great merit and much truth. Yet I am clearly of the opinion that it was merely from his love of symmetry that Kant deduced as necessary the conception of the soul from the paralogism of substantiality by applying the demand for the unconditioned to the conception *substance*, which is the first category of relation, and accordingly maintained that the conception of a soul arose in this way in every speculative reason. If this conception really had its origin in the presupposition of a final subject of all predicates of a thing, one would have assumed a soul not in men alone, but also just as necessarily in every lifeless thing, for such a thing also requires a final subject of all its predicates. Speaking generally, however, Kant makes use of a quite inadmissible expression when he talks of something which can exist only as

subject and not as predicate (*e.g.*, Critique of Pure Reason, p. 323; V. 412; Prolegomena, § 4 and 47); though a precedent for this is to be found in Aristotle's "Metaphysics," iv. ch. 8. Nothing whatever exists as subject and predicate, for these expressions belong exclusively to logic, and denote the relations of abstract conceptions to each other. Now their correlative or representative in the world of perception must be substance and accident. But then we need not look further for that which exists always as substance and never as accident, but have it directly in matter. It is the substance corresponding to all properties of things which are their accidents. It is, in fact, if one wishes to retain the expression of Kant which has just been condemned, the final subject of all predicates of that empirically given thing, that which remains after the abstraction of all its properties of every kind. And this holds good of man as of a brute, a plant, or a stone, and is so evident, that in order not to see it a determined desire not to see is required. That it is really the prototype of the conception substance, I will show soon. But subject and predicate are related to substance and accident rather as the principle of sufficient reason in logic to the law of causality in nature, and the substitution or identification of the former is just as inadmissible as that of the latter. Yet in the "Prolegomena," § 46, Kant carries this substitution and identification to its fullest extent in order to make the conception of the soul arise from that of the final subject of all predicates and from the form of the categorical syllogism. In order to discover the sophistical nature of this paragraph, one only needs to reflect that subject and predicate are purely logical determinations, which concern abstract conceptions solely and alone, and that according to their relation in the judgment. Substance and accident, on the other hand, belong to the world of perception and its apprehension in the understanding, and are even there only as identical with matter and form or quality. Of this more shortly.

The antithesis which has given occasion for the assumption of two fundamentally different substances, body and soul, is in truth that of objective and subjective. If a man apprehends himself objectively in external perception, he finds a being extended in space and in general merely corporeal; but if, on the other hand, he apprehends himself in mere self-consciousness, thus purely subjectively, he finds himself a merely willing and perceiving being, free from all forms of perception, thus also without a single one of the properties which belong to bodies. Now he forms the conception of the soul, like all the transcendental conceptions

called by Kant Ideas, by applying the principle of sufficient reason, the form of all objects, to that which is not an object, and in this case indeed to the subject of knowing and willing. He treats, in fact, knowing, thinking, and willing as effects of which he seeks the cause, and as he cannot accept the body as their cause, he assumes a cause of them entirely different from the body. In this manner the first and the last of the dogmatists proves the existence of the soul: Plato in the "Phædrus" and also Wolf: from thinking and willing as the effects which lead to that cause. Only after in this way, by hypostatising a cause corresponding to the effect, the conception of an immaterial, simple, indestructible being had arisen, the school developed and demonstrated this from the conception of *substance*. But this conception itself they had previously constructed specially for this purpose by the following artifice, which is worthy of notice.

With the first class of ideas, *i.e.*, the real world of perception, the idea of matter is also given; because the law governing this class of ideas, the law of causality, determines the change of the states or conditions, and these conditions themselves presuppose something permanent, whose changes they are. When speaking above of the principle of the permanence of substance, I showed, by reference to earlier passages, that this idea of matter arises because in the understanding, for which alone it exists, time and space are intimately united, and the share of space in this product exhibits itself as the permanence of matter, while the share of time appears as the change of states. Purely in itself, matter can only be thought *in abstracto*, and not perceived; for to perception it always appears already in form and quality. From this conception of *matter*, *substance* is again an abstraction, consequently a higher *genus*, and arose in this way. Of the conception of matter, only the predicate of permanence was allowed to remain, while all its other essential properties, extension, impenetrability, divisibility, &c., were thought away. Like every higher *genus*, then, the concept *substance* contains *less in itself* than the concept *matter*, but, unlike every other higher *genus*, it does not contain *more under it*, because it does not include several lower *genera* besides matter; but this remains the one true species of the concept substance, the only assignable thing by which its content is realised and receives a proof. Thus the aim with which in other cases the reason produces by abstraction a higher conception, in order that in it several subordinate species may be thought at once through common determinations, has here no place; consequently that abstraction is either

undertaken idly and entirely without aim, or it has a secret secondary purpose. This secret purpose is now brought to light; for under the conception substance, along with its true sub-species matter, a second species is co-ordinated — the immaterial, simple, indestructible substance, soul. But the surreptitious introduction of this last concept arose from the fact that the higher concept *substance* was framed illogically, and in a manner contrary to law. In its legitimate procedure the reason always frames the concept of a higher genus by placing together the concepts of several species, and now comparing them, proceeds discursively, and by omitting their differences and retaining the qualities in which they agree, obtains the generic concept which includes them all but has a smaller content. From this it follows that the concepts of the species must always precede the concept of the genus. But, in the present case, the converse is true. Only the concept matter existed before the generic concept *substance*. The latter was without occasion, and consequently without justification, as it were aimlessly framed from the former by the arbitrary omission of all its determinations except one. Not till afterwards was the second ungenuine species placed beside the concept matter, and so foisted in. But for the framing of this second concept nothing more was now required than an express denial of what had already been tacitly omitted in the higher generic concept, extension, impenetrability, and divisibility. Thus the concept *substance* was framed merely to be the vehicle for the surreptitious introduction of the concept of the immaterial substance. Consequently, it is very far from being capable of holding good as a category or necessary function of the understanding; rather is it an exceedingly superfluous concept, because its only true content lies already in the concept of matter, besides which it contains only a great void, which can be filled up by nothing but the illicitly introduced species *immaterial substance*; and, indeed, it was solely for the purpose of containing this that it was framed. Accordingly, in strictness, the concept substance must be entirely rejected, and the concept matter everywhere put in its place.

The categories were a procrustean bed for every possible thing, but the three kinds of syllogisms are so only for the three so-called Ideas. The Idea of the soul was compelled to find its origin in the form of the categorical syllogism. It is now the turn of the dogmatic ideas concerning the universe, so far as it is thought as an object in itself, between two limits — that of the

smallest (atom), and that of the largest (limits of the universe in time and space). These must now proceed from the form of the hypothetical syllogism. Nor for this in itself is any special violence necessary. For the hypothetical judgment has its form from the principle of sufficient reason, and not the cosmological alone but all those so-called Ideas really have their origin in the inconsiderate and unrestricted application of that principle, and the laying aside of it at pleasure. For, in accordance with that principle, the mere dependence of an object upon another is ever sought for, till finally the exhaustion of the imagination puts an end to the journey; and thus it is lost sight of that every object, and indeed the whole chain of objects and the principle of sufficient reason itself, stand in a far closer and greater dependence, the dependence upon the knowing subject, for whose objects alone, *i.e.*, ideas, that principle is valid, for their mere position in space and time is determined by it. Thus, since the form of knowledge from which here merely the cosmological Ideas are derived, the principle of sufficient reason, is the source of all subtle hypostases, in this case no sophisms need be resorted to; but so much the more is sophistry required in order to classify those Ideas according to the four titles of the categories.

(1.) The cosmological Ideas with regard to time and space, thus of the limits of the world in both, are boldly regarded as determined through the category of *quantity*, with which they clearly have nothing in common, except the accidental denotation in logic of the extent of the concept of the subject in the judgment by the word *quantity*, a pictorial expression instead of which some other might just as well have been chosen. But for Kant's love of symmetry this is enough. He takes advantage of the fortunate accident of this nomenclature, and links to it the transcendent dogmas of the world's extension.

(2.) Yet more boldly does Kant link to *quality*, *i.e.*, the affirmation or negation in a judgment, the transcendent Ideas concerning matter; a procedure which has not even an accidental similarity of words as a basis. For it is just to the *quantity*, and not to the *quality* of matter that its mechanical (not chemical) divisibility is related. But, what is more, this whole idea of divisibility by no means belongs to those inferences according to the principle of sufficient reason, from which, however, as the content of the hypothetical form, all cosmological Ideas ought to flow. For the assertion upon which Kant there relies, that the relation of the parts to the whole is that of the condition to the conditioned, thus a relation

according to the principle of sufficient reason, is certainly an ingenious but yet a groundless sophism. That relation is rather based upon the principle of contradiction; for the whole is not through the part, nor the parts through the whole, but both are necessarily together because they are one, and their separation is only an arbitrary act. It depends upon this, according to the principle of contradiction, that if the parts are thought away, the whole is also thought away, and conversely; and by no means upon the fact that the parts as the *reason* conditioned the whole as the *consequent*, and that therefore, in accordance with the principle of sufficient reason, we were necessarily led to seek the ultimate parts, in order, as its reason, to understand from them the whole. Such great difficulties are here overcome by the love of symmetry.

(3.) The Idea of the first cause of the world would now quite properly come under the title of *relation*; but Kant must reserve this for the fourth title, that of *modality*, for which otherwise nothing would remain, and under which he forces this idea to come by saying that the contingent (*i.e.*, according to his explanation, which is diametrically opposed to the truth, every consequent of its reason) becomes the necessary through the first cause. Therefore, for the sake of symmetry, the conception of *freedom* appears here as the third Idea. By this conception, however, as is distinctly stated in the observations on the thesis of the third conflict, what is really meant is only that Idea of the cause of the world which alone is admissible here. The third and fourth conflicts are at bottom tautological.

About all this, however, I find and assert that the whole antinomy is a mere delusion, a sham fight. Only the assertions of the antitheses really rest upon the forms of our faculty of knowledge, *i.e.*, if we express it objectively, on the necessary, *a priori* certain, most universal laws of nature. Their proofs alone are therefore drawn from objective grounds. On the other hand, the assertions and proofs of the theses have no other than a subjective ground, rest solely on the weakness of the reasoning individual; for his imagination becomes tired with an endless regression, and therefore he puts an end to it by arbitrary assumptions, which he tries to smooth over as well as he can; and his judgment, moreover, is in this case paralysed by early and deeply imprinted prejudices. On this account the proof of the thesis in all the four conflicts is throughout a mere sophism, while that of the antithesis is a necessary inference of the reason from the laws of the world as idea known to us *a priori*. It is, moreover, only with great pains and skill that

Kant is able to sustain the thesis, and make it appear to attack its opponent, which is endowed with native power. Now in this regard his first and constant artifice is, that he does not render prominent the *nervus argumentationis*, and thus present it in as isolated, naked, and distinct a manner as he possibly can; but rather introduces the same argument on both sides, concealed under and mixed up with a mass of superfluous and prolix sentences.

The theses and antitheses which here appear in such conflict remind one of the δικαιος and αδικος λογος which Socrates, in the "Clouds" of Aristophanes, brings forward as contending. Yet this resemblance extends only to the form and not to the content, though this would gladly be asserted by those who ascribe to these most speculative of all questions of theoretical philosophy an influence upon morality, and therefore seriously regard the thesis as the δικαιος, and the antithesis as the αδικος λογος. I shall not, however, accommodate myself here with reference to such small, narrow, and perverse minds; and, giving honour not to them, but to the truth, I shall show that the proofs which Kant adduced of the individual theses are sophisms, while those of the antitheses are quite fairly and correctly drawn from objective grounds. I assume that in this examination the reader has always before him the Kantian antinomy itself.

If the proof of the thesis in the first conflict is to be held as valid, then it proves too much, for it would be just as applicable to time itself as to change in time, and would therefore prove that time itself must have had a beginning, which is absurd. Besides, the sophism consists in this, that instead of the beginninglessness of the series of states, which was at first the question, suddenly the endlessness (infinity) of the series is substituted; and now it is proved that this is logically contradicted by completeness, and yet every present is the end of the past, which no one doubted. The end of a beginningless series can, however, always be *thought*, without prejudice to the fact that it has no beginning; just as, conversely, the beginning of an endless series can also be *thought*. But against the real, true argument of the antithesis, that the changes of the world necessarily presuppose an infinite series of changes *backwards*, absolutely nothing is advanced. We can think the possibility that the causal chain will some day end in an absolute standstill, but we can by no means think the possibility of an absolute beginning.[8]

With reference to the spatial limits of the world, it is proved that, if it is to be regarded as a *given whole*, it must necessarily have limits. The reasoning is correct, only it was just the first link of it that was to be proved, and that remains unproved. Totality presupposes limits, and limits presuppose totality; but here both together are arbitrarily presupposed. For this second point, however, the antithesis affords no such satisfactory proof as for the first, because the law of causality provides us with necessary determinations only with reference to time, not to space, and affords us *a priori* the certainty that no occupied time can ever be bounded by a previous empty time, and that no change can be the first change, but not that an occupied space can have no empty space beside it. So far no *a priori* decision on the latter point would be possible; yet the difficulty of conceiving the world in space as limited lies in the fact that space itself is necessarily infinite, and therefore a limited finite world in space, however large it may be, becomes an infinitely small magnitude; and in this incongruity the imagination finds an insuperable stumbling-block, because there remains for it only the choice of thinking the world either as infinitely large or infinitely small. This was already seen by the ancient philosophers: Μητροδωρος, ὁ καθηγητης Επικουρου, φηδιν ατοπον ειναι εν μεγαλῳ πεδιῳ ἑνα σταχυν γεννηθηναι, και ἑνα κοσμον εν τῳ απειρῳ (*Metrodorus, caput scholæ Epicuri, absurdum ait, in magno campo spicam unam produci, et unum in infinito mundum*) Stob. Ecl., i. c. 23. Therefore many of them taught (as immediately follows), απειρους κοσμους εν τῳ απειρῳ (*infinitos mundos in infinito*). This is also the sense of the Kantian argument for the antithesis, only he has disfigured it by a scholastic and ambiguous expression. The same argument might be used against the limitation of the world in time, only we have a far better one under the guidance of causality. In the case of the assumption of a world limited in space, there arises further the unanswerable question, What advantage has the filled part of space enjoyed over the infinite space that has remained empty? In the fifth dialogue of his book, "*Del Infinito, Universo e Mondi*," Giordano Bruno gives a full account of the arguments for and against the finiteness of the world, which is very well worth reading. For the rest, Kant himself asserts seriously, and upon objective grounds, the infinity of the world in space in his "Natural History of the Theory of the Heavens," part ii. ch. 7. Aristotle also acknowledges the same, "Phys.," iii. ch. 4, a chapter which, together

with the following one, is very well worth reading with reference to this antinomy.

In the second conflict the thesis is at once guilty of a very palpable *petitio principii*, for it commences, “Every *compound* substance consists of simple parts.” From the compoundness here arbitrarily assumed, no doubt it afterwards very easily proves the simple parts. But the proposition, “All matter is compound,” which is just the point, remains unproved, because it is simply a groundless assumption. The opposite of simple is not compound, but extended, that which has parts and is divisible. Here, however, it is really tacitly assumed that the parts existed before the whole, and were brought together, whence the whole has arisen; for this is the meaning of the word “compound.” Yet this can just as little be asserted as the opposite. Divisibility means merely the possibility of separating the whole into parts, and not that the whole is compounded out of parts and thus came into being. Divisibility merely asserts the parts *a parte post*; compoundness asserts them *a parte ante*. For there is essentially no temporal relation between the parts and the whole; they rather condition each other reciprocally, and thus always exist at the same time, for only so far as both are there is there anything extended in space. Therefore what Kant says in the observations on the thesis, “Space ought not to be called a *compositum*, but a *totum*,” &c., holds good absolutely of matter also, which is simply space become perceptible. On the other hand, the infinite divisibility of matter, which the antithesis asserts, follows *a priori* and incontrovertibly from that of space, which it fills. This proposition has absolutely nothing against it; and therefore Kant also (p. 513; V. 541), when he speaks seriously and in his own person, no longer as the mouthpiece of the αδικος λογος, presents it as objective truth; and also in the “Metaphysical First Principles of Natural Science” (p. 108, first edition), the proposition, “Matter is infinitely divisible,” is placed at the beginning of the proof of the first proposition of mechanics as established truth, having appeared and been proved as the fourth proposition in the Dynamics. But here Kant spoils the proof of the antithesis by the greatest obscurity of style and useless accumulation of words, with the cunning intention that the evidence of the antithesis shall not throw the sophisms of the thesis too much into the shade. Atoms are no necessary thought of the reason, but merely an hypothesis for the explanation of the difference of the specific gravity of bodies. But Kant himself has shown, in the dynamics of his

"Metaphysical First Principles of Natural Science," that this can be otherwise, and indeed better and more simply explained than by atomism. In this, however, he was anticipated by Priestley, "On Matter and Spirit," sect. i. Indeed, even in Aristotle, "Phys." iv. 9, the fundamental thought of this is to be found.

The argument for the third thesis is a very fine sophism, and is really Kant's pretended principle of pure reason itself entirely unadulterated and unchanged. It tries to prove the finiteness of the series of causes by saying that, in order to be *sufficient*, a cause must contain the complete sum of the conditions from which the succeeding state, the effect, proceeds. For the completeness of the determinations present *together* in the state which is the cause, the argument now substitutes the completeness of the series of causes by which that state itself was brought to actuality; and because completeness presupposes the condition of being rounded off or closed in, and this again presupposes finiteness, the argument infers from this a first cause, closing the series and therefore unconditioned. But the juggling is obvious. In order to conceive the state A. as the sufficient cause of the state B., I assume that it contains the sum of the necessary determinations from the co-existence of which the estate B. inevitably follows. Now by this my demand upon it as a *sufficient* cause is entirely satisfied, and has no direct connection with the question how the state A. itself came to be; this rather belongs to an entirely different consideration, in which I regard the said state A. no more as cause, but as itself an effect; in which case another state again must be related to it, just as it was related to B. The assumption of the finiteness of the series of causes and effects, and accordingly of a first beginning, appears nowhere in this as necessary, any more than the presentness of the present moment requires us to assume a beginning of time itself. It only comes to be added on account of the laziness of the speculating individual. That this assumption lies in the acceptance of a cause as a *sufficient reason* is thus unfairly arrived at and false, as I have shown at length above when considering the Kantian principle of pure reason which coincides with this thesis. In illustration of the assertion of this false thesis, Kant is bold enough in his observations upon it to give as an example of an unconditioned beginning his rising from his chair; as if it were not just as impossible for him to rise without a motive as for a ball to roll without a cause. I certainly do not need to prove the baselessness of the appeal which, induced by a sense of weakness, he makes to the

philosophers of antiquity, by quoting from Ocellus Lucanus, the Eleatics, &c., not to speak of the Hindus. Against the proof of this antithesis, as in the case of the previous ones, there is nothing to advance.

The fourth conflict is, as I have already remarked, really tautological with the third; and the proof of the thesis is also essentially the same as that of the preceding one. His assertion that every conditioned presupposes a complete series of conditions, and therefore a series which ends with an unconditioned, is a *petitio principii*, which must simply be denied. Everything conditioned presupposes nothing but its condition; that this is again conditioned raises a new consideration which is not directly contained in the first.

A certain appearance of probability cannot be denied to the antinomy; yet it is remarkable that no part of the Kantian philosophy has met so little contradiction, indeed has found so much acceptance, as this exceedingly paradoxical doctrine. Almost all philosophical parties and text-books have regarded it as valid, and have also repeatedly reconstructed it; while nearly all Kant's other doctrines have been contested, and indeed there have never been wanting some perverse minds which rejected even the transcendental æsthetic. The undivided assent which the antinomy, on the other hand, has met with may ultimately arise from the fact that certain persons regard with inward satisfaction the point at which the understanding is so thoroughly brought to a standstill, having hit upon something which at once is and is not, so that they actually have before them here the sixth trick of Philadelphia in Lichtenberg's broadsheet.

If we examine the real meaning of Kant's *Critical Solution* of the cosmological problem which now follows, we find that it is not what he gives it out to be, the solution of the problem by the disclosure that both sides, starting from false assumptions, are wrong in the first and second conflicts, and that in the third and fourth both are right. It is really the confirmation of the antitheses by the explanation of their assertions.

First Kant asserts, in this solution, obviously wrongly, that both sides started from the assumption, as their first principle, that with the conditioned the completed (thus rounded off) *series* of its conditions is given. Only the thesis laid down this proposition, Kant's principle of pure reason, as the ground of its assertions; the antithesis, on the other hand, expressly denied it throughout, and asserted the contrary. Further, Kant charges both sides with this assumption, that the world exists in itself, *i.e.*,

independently of being known and of the forms of this knowledge, but this assumption also is only made by the thesis; indeed, it is so far from forming the ground of the assertions of the antithesis that it is absolutely inconsistent with them. For that it should all be given is absolutely contradictory of the conception of an infinite series. It is therefore essential to it that it should always exist only with reference to the process of going through it, and not independently of this. On the other hand, in the assumption of definite limits also lies that of a whole which exists absolutely and independently of the process of completely measuring it. Thus it is only the thesis that makes the false assumption of a self-existent universe, *i.e.*, a universe given prior to all knowledge, and to which knowledge came as to something external to itself. The antithesis from the outset combats this assumption absolutely; for the infinity of the series which it asserts merely under the guidance of the principle of sufficient reason can only exist if the regressus is fully carried out, but not independently of it. As the object in general presupposes the subject, so also the object which is determined as an *endless* chain of conditions necessarily presupposes in the subject the kind of knowledge corresponding to this, that is, the *constant following* of the links of that chain. But this is just what Kant gives as the solution of the problem, and so often repeats: "The infinity of the world is only *through* the regressus, not *before* it." This his solution of the conflict is thus really only the decision in favour of the antithesis in the assertion of which this truth already lies, while it is altogether inconsistent with the assertions of the thesis. If the antithesis had asserted that the world consisted of infinite series of reasons and consequents, and yet existed independently of the idea and its regressive series, thus in itself, and therefore constituted a given whole, it would have contradicted not only the thesis but also itself. For an infinite can never be given as a whole, nor an *endless* series exist, except as an endless progress; nor can what is boundless constitute a whole. Thus this assumption, of which Kant asserts that it led both sides into error, belongs only to the thesis.

It is already a doctrine of Aristotle's that an infinity can never be *actu*, *i.e.*, actual and given, but only *potentiâ*. Ουκ εστιν ενεργειᾳ ειναι το απειρον ... αλλ᾽ αδυνατον το εντελεχειᾳ ον απειρον (*infinitum non potest esse actu: ... sed impossibile, actu esse infinitum*), Metaph. K. 10. Further: κατ᾽ ενεργειαν μεν γαρ ουδεν εστιν απειρον, δυναμει δε επι την διαιρεσιν

(*nihil enim actu infinitum est, sed potentia tantum, nempe divisione ipsa*). *De generat. et corrupt.*, i., 3. He develops this fully in the "Physics," iii. 5 and 6, where to a certain extent he gives the perfectly correct solution of the whole of the antinomies. He expounds the antinomies in his short way, and then says, "A mediator (διαιτητου) is required;" upon which he gives the solution that the infinite, both of the world in space and in time and in division, is never *before* the regressus, or progressus, but in it. This truth lies then in the rightly apprehended conception of the infinite. Thus one misunderstands himself if he imagines that he can think the infinite, of whatever kind it may be, as something objectively present and complete, and independent of the regressus.

Indeed if, reversing the procedure, we take as the starting-point what Kant gives as the solution of the conflict, the assertion of the antithesis follows exactly from it. Thus: if the world is not an unconditioned whole and does not exist absolutely but only in the idea, and if its series of reasons and consequents do not exist *before* the regressus of the ideas of them but only *through* this regressus, then the world cannot contain determined and finite series, because their determination and limitation would necessarily be independent of the idea, which would then only come afterwards; but all its series must be infinite, *i.e.*, inexhaustible by any idea.

On p. 506; V. 534, Kant tries to prove from the falseness of both sides the transcendental ideality of the phenomenon, and begins, "If the world is a whole existing by itself, it is either finite or infinite." But this is false; a whole existing of itself cannot possibly be infinite. That ideality may rather be concluded from the infinity of the series in the world in the following manner: — If the series of reasons and consequents in the world are absolutely without end, the world cannot be a given whole independent of the idea; for such a world always presupposes definite limits, just as on the contrary infinite series presuppose an infinite regressus. Therefore, the presupposed infinity of the series must be determined through the form of reason and consequent, and this again through the form of knowledge of the subject; thus the world as it is known must exist only in the idea of the subject.

Now whether Kant himself was aware or not that his critical solution of the problem is really a decision in favour of the antithesis, I am unable to decide. For it depends upon whether what Schelling has somewhere very happily called Kant's system of accommodation extended so far; or whether Kant's mind was here already involved in an unconscious accommodation to the influence of his time and surroundings.

The solution of the third antinomy, the subject of which was the Idea of freedom, deserves a special consideration, because it is for us very well worth notice that it is just here in connection with *the Idea of freedom* that Kant is obliged to speak more fully of the *thing in itself*, which was hitherto only seen in the background. This is very explicable to us since we have recognised the thing in itself as the *will*. Speaking generally, this is the point at which the Kantian philosophy leads to mine, or at which mine springs out

of his as its parent stem. One will be convinced of this if one reads with attention pp. 536 and 537; V. 564 and 565, of the "Critique of Pure Reason," and, further, compares these passages with the introduction to the "Critique of Judgment," pp. xviii. and xix. of the third edition, or p. 13 of Rosenkranz's edition, where indeed it is said: "The conception of freedom can in its object (that is then the will) present to the mind a thing in itself, but not in perception; the conception of nature, on the other hand, can present its object to the mind in perception, but not as a thing in itself." But specially let any one read concerning the solution of the antinomies the fifty-third paragraph of the Prolegomena, and then honestly answer the question whether all that is said there does not sound like a riddle to which my doctrine is the answer. Kant never completed his thought; I have merely carried out his work. Accordingly, what Kant says only of the human phenomenon I have extended to all phenomena in general, as differing from the human phenomenon only in degree, that their true being is something absolutely free, *i.e.*, a will. It appears from my work how fruitful this insight is in connection with Kant's doctrine of the ideality of space, time, and causality.

Kant has nowhere made the thing in itself the subject of a special exposition or distinct deduction; but, whenever he wants it, he introduces it at once by means of the conclusion that the phenomenon, thus the visible world, must have a reason, an intelligible cause, which is not a phenomenon, and therefore belongs to no possible experience. He does this after having assiduously insisted that the categories, and thus causality also, had a use which was absolutely confined to possible experience; that they were merely forms of the understanding, which served to spell out the phenomena of the world of sense, beyond which, on the other hand, they had no significance, &c., &c. Therefore, he denies in the most uncompromising manner their application to things beyond experience, and rightly explains and at once rejects all earlier dogmatism as based upon the neglect of this law. The incredible inconsistency which Kant here fell into was soon noticed, and used by his first opponents to make attacks on his philosophy to which it could offer no resistance. For certainly we apply the law of causality entirely *a priori* and before all experience to the changes felt in our organs of sense. But, on this very account, this law is just as much of subjective origin as these sensations themselves, and thus does not lead to a thing in itself. The truth is, that upon the path of the idea one can

never get beyond the idea; it is a rounded-off whole, and has in its own resources no clue leading to the nature of the thing in itself, which is *toto genere* different from it. If we were merely perceiving beings, the way to the thing in itself would be absolutely cut off from us. Only the other side of our own being can disclose to us the other side of the inner being of things. This path I have followed. But Kant's inference to the thing in itself, contrary as it is to his own teaching, obtains some excuse from the following circumstance. He does not say, as truth required, simply and absolutely that the object is conditioned by the subject, and conversely; but only that the manner of the appearance of the object is conditioned by the forms of knowledge of the subject, which, therefore, also come *a priori* to consciousness. But that now which in opposition to this is only known *a posteriori* is for him the immediate effect of the thing in itself, which becomes phenomenon only in its passage through these forms which are given *a priori*. From this point of view it is to some extent explicable how it could escape him that objectivity in general belongs to the form of the phenomenon, and is just as much conditioned by subjectivity in general as the mode of appearing of the object is conditioned by the forms of knowledge of the subject; that thus if a thing in itself must be assumed, it absolutely cannot be an object, which however he always assumes it to be, but such a thing in itself must necessarily lie in a sphere *toto genere* different from the idea (from knowing and being known), and therefore could least of all be arrived at through the laws of the combination of objects among themselves.

With the proof of the thing in itself it has happened to Kant precisely as with that of the *a priori* nature of the law of causality. Both doctrines are true, but their proof is false. They thus belong to the class of true conclusions from false premises. I have retained them both, but have proved them in an entirely different way, and with certainty.

The thing in itself I have neither introduced surreptitiously nor inferred according to laws which exclude it, because they really belong to its phenomenal appearance; nor, in general, have I arrived at it by roundabout ways. On the contrary, I have shown it directly, there where it lies immediately, in the will, which reveals itself to every one directly as the in-itself of his own phenomenal being.

And it is also this immediate knowledge of his own will out of which in human consciousness the conception of *freedom* springs; for certainly the

will, as world-creating, as thing in itself, is free from the principle of sufficient reason, and therewith from all necessity, thus is completely independent, free, and indeed almighty. Yet, in truth, this only holds good of the will in itself, not of its manifestations, the individuals, who, just through the will itself, are unalterably determined as its manifestations in time. But in the ordinary consciousness, unenlightened by philosophy, the will is at once confused with its manifestation, and what belongs only to the former is attributed to the latter, whence arises the illusion of the unconditioned freedom of the individual. Therefore Spinoza says rightly that if the projected stone had consciousness, it would believe that it flew of its own free will. For certainly the in-itself of the stone also is the will, which alone is free; but, as in all its manifestations, here also, where it appears as a stone, it is already fully determined. But of all this enough has already been said in the text of this work.

Kant fails to understand and overlooks this immediate origin of the conception of freedom in every human consciousness, and therefore he now places (p. 533; V. 561) the source of that conception in a very subtle speculation, through which the unconditioned, to which the reason must always tend, leads us to hypostatise the conception of freedom, and it is only upon this transcendent Idea of freedom that the practical conception of it is supposed to be founded. In the "Critique of Practical Reason," § 6, and p. 158 of the fourth and 235 of Rosenkranz's edition, he yet deduces this last conception differently by saying that the categorical imperative presupposes it. The speculative Idea is accordingly only the primary source of the conception of freedom for the sake of this presupposition, but here it obtains both significance and application. Neither, however, is the case. For the delusion of a perfect freedom of the individual in his particular actions is most lively in the conviction of the least cultivated man who has never reflected, and it is thus founded on no speculation, although often assumed by speculation from without. Thus only philosophers, and indeed only the most profound of them, are free from it, and also the most thoughtful and enlightened of the writers of the Church.

It follows, then, from all that has been said, that the true source of the conception of freedom is in no way essentially an inference, either from the speculative Idea of an unconditioned cause, nor from the fact that it is presupposed by the categorical imperative. But it springs directly from the consciousness in which each one recognises himself at once as the *will*, *i.e.*,

as that which, as the thing in itself, has not the principle of sufficient reason for its form, and which itself depends upon nothing, but on which everything else rather depends. Every one, however, does not recognise himself at once with the critical and reflective insight of philosophy as a determined manifestation of this will which has already entered time, as we might say, an act of will distinguished from that will to live itself; and, therefore, instead of recognising his whole existence as an act of his freedom, he rather seeks for freedom in his individual actions. Upon this point I refer the reader to my prize-essay on the freedom of the will.

Now if Kant, as he here pretends, and also apparently did in earlier cases, had merely inferred the thing in itself, and that with the great inconsistency of an inference absolutely forbidden by himself, what a remarkable accident would it then be that here, where for the first time he approaches the thing in itself more closely and explains it, he should recognise in it at once the *will*, the free will showing itself in the world only in temporal manifestations! I therefore really assume, though it cannot be proved, that whenever Kant spoke of the thing in itself, in the obscure depths of his mind he already always indistinctly thought of the will. This receives support from a passage in the preface to the second edition of the "Critique of Pure Reason," pp. xxvii. and xxviii., in Rosenkranz's edition, p. 677 of the Supplement.

For the rest, it is just this predetermined solution of the sham third conflict that affords Kant the opportunity of expressing very beautifully the deepest thoughts of his whole philosophy. This is the case in the whole of the "Sixth Section of the Antinomy of Pure Reason;" but, above all, in the exposition of the opposition between the empirical and the intelligible character, p. 534-550; V. 562-578, which I number among the most admirable things that have ever been said by man. (As a supplemental explanation of this passage, compare a parallel passage in the Critique of Practical Reason, p. 169-179 of the fourth edition, or p. 224-231 of Rosenkranz's edition.) It is yet all the more to be regretted that this is here not in its right place, partly because it is not found in the way which the exposition states, and therefore could be otherwise deduced than it is, partly because it does not fulfil the end for which it is there — the solution of the sham antinomy. The intelligible character, the thing in itself, is inferred from the phenomenon by the inconsistent use of the category of causality beyond the sphere of all phenomena, which has already been sufficiently

condemned. In this case the will of man (which Kant entitles reason, most improperly, and with an unpardonable breach of all use of language) is set up as the thing in itself, with an appeal to an unconditioned ought, the categorical imperative, which is postulated without more ado.

Now, instead of all this, the plain open procedure would have been to start directly from the will, and prove it to be the in-itself of our own phenomenal being, recognised without any mediation; and then to give that exposition of the empirical and the intelligible character to explain how all actions, although necessitated by motives, yet, both by their author and by the disinterested judge, are necessarily and absolutely ascribed to the former himself and alone, as depending solely upon him, to whom therefore guilt and merit are attributed in respect of them. This alone was the straight path to the knowledge of that which is not phenomenon, and therefore will not be found by the help of the laws of the phenomenon, but is that which reveals itself through the phenomenon, becomes knowable, objectifies itself — the will to live. It would then have had to be exhibited merely by analogy as the inner nature of every phenomenon. Then, however, it certainly could not have been said that in lifeless or even animal nature no faculty can be thought except as sensuously conditioned (p. 546; V. 574), which in Kant's language is simply saying that the explanation, according to the law of causality, exhausts the inner nature of these phenomena, and thus in their case, very inconsistently, the thing in itself disappears. Through the false position and the roundabout deduction according with it which the exposition of the thing in itself has received from Kant, the whole conception of it has also become falsified. For the will or the thing in itself, found through the investigation of an unconditioned cause, appears here related to the phenomenon as cause to effect. But this relation exists only within the phenomenal world, therefore presupposes it, and cannot connect the phenomenal world itself with what lies outside it, and is *toto genere* different from it.

Further, the intended end, the solution of the third antinomy by the decision that both sides, each in a different sense, are right, is not reached at all. For neither the thesis nor the antithesis have anything to do with the thing in itself, but entirely with the phenomenon, the objective world, the world as idea. This it is, and absolutely nothing else, of which the thesis tries to show, by means of the sophistry we have laid bare, that it contains unconditioned causes, and it is also this of which the antithesis rightly

denies that it contains such causes. Therefore the whole exposition of the transcendental freedom of the will, so far as it is a thing in itself, which is given here in justification of the thesis, excellent as it is in itself, is yet here entirely a μεταβασις εις αλλο γενος. For the transcendental freedom of the will which is expounded is by no means the unconditioned causality of a cause, which the thesis asserts, because it is of the essence of a cause that it must be a phenomenon, and not something which lies beyond all phenomena and is *toto genere* different.

If what is spoken of is cause and effect, the relation of the will to the manifestation (or of the intelligible character to the empirical) must never be introduced, as happens here: for it is entirely different from causal relation. However, here also, in this solution of the antinomy, it is said with truth that the empirical character of man, like that of every other cause in nature, is unalterably determined, and therefore that his actions necessarily take place in accordance with the external influences; therefore also, in spite of all transcendental freedom (*i.e.*, independence of the will in itself of the laws of the connection of its manifestation), no man has the power of himself to begin a series of actions, which, however, was asserted by the thesis. Thus also freedom has no causality; for only the will is free, and it lies outside nature or the phenomenon, which is just its objectification, but does not stand in a causal relation to it, for this relation is only found within the sphere of the phenomenon, thus presupposes it, and cannot embrace the phenomenon itself and connect it with what is expressly not a phenomenon. The world itself can only be explained through the will (for it is the will itself, so far as it manifests itself), and not through causality. But *in the world* causality is the sole principle of explanation, and everything happens simply according to the laws of nature. Thus the right lies entirely on the side of the antithesis, which sticks to the question in hand, and uses that principle of explanation which is valid with regard to it; therefore it needs no apology. The thesis, on the other hand, is supposed to be got out of the matter by an apology, which first passes over to something quite different from the question at issue, and then assumes a principle of explanation which is inapplicable to it.

The fourth conflict is, as has already been said, in its real meaning tautological with the third. In its solution Kant develops still more the untenable nature of the thesis; while for its truth, on the other hand, and its pretended consistency with the antithesis, he advances no reason, as

conversely he is able to bring no reason against the antithesis. The assumption of the thesis he introduces quite apologetically, and yet calls it himself (p. 562; V. 590) an arbitrary presupposition, the object of which might well in itself be impossible, and shows merely an utterly impotent endeavour to find a corner for it somewhere where it will be safe from the prevailing might of the antithesis, only to avoid disclosing the emptiness of the whole of his once-loved assertion of the necessary antinomy in human reason.

Now follows the chapter on the transcendental ideal, which carries us back at once to the rigid Scholasticism of the Middle Ages. One imagines one is listening to Anselm of Canterbury himself. The *ens realissimum*, the essence of all realities, the content of all affirmative propositions, appears, and indeed claims to be a necessary thought of the reason. I for my part must confess that to my reason such a thought is impossible, and that I am not able to think anything definite in connection with the words which denote it.

Moreover, I do not doubt that Kant was compelled to write this extraordinary chapter, so unworthy of him, simply by his fondness for architectonic symmetry. The three principal objects of the Scholastic philosophy (which, as we have said, if understood in the wider sense, may be regarded as continuing down to Kant), the soul, the world, and God, are supposed to be deduced from the three possible major propositions of syllogisms, though it is plain that they have arisen, and can arise, simply and solely through the unconditioned application of the principle of sufficient reason. Now, after the soul had been forced into the categorical judgment, and the hypothetical was set apart for the world, there remained for the third Idea nothing but the disjunctive major. Fortunately there existed a previous work in this direction, the *ens realissimum* of the Scholastics, together with the ontological proof of the existence of God set up in a rudimentary form by Anselm of Canterbury and then perfected by Descartes. This was joyfully made use of by Kant, with some reminiscence also of an earlier Latin work of his youth. However, the sacrifice which Kant makes to his love of architectonic symmetry in this chapter is exceedingly great. In defiance of all truth, what one must regard as the grotesque idea of an essence of all possible realities is made an essential and necessary thought of the reason. For the deduction of this Kant makes

use of the false assertion that our knowledge of particular things arises from a progressive limitation of general conceptions; thus also of a most general conception of all which contains all reality *in itself*. In this he stands just as much in contradiction with his own teaching as with the truth, for exactly the converse is the case. Our knowledge starts with the particular and is extended to the general, and all general conceptions arise by abstraction from real, particular things known by perception, and this can be carried on to the most general of all conceptions, which includes everything under it, but almost nothing *in it*. Thus Kant has here placed the procedure of our faculty of knowledge just upside down, and thus might well be accused of having given occasion to a philosophical charlatanism that has become famous in our day, which, instead of recognising that conceptions are thoughts abstracted from things, makes, on the contrary the conceptions first, and sees in things only concrete conceptions, thus bringing to market the world turned upside down as a philosophical buffoonery, which of course necessarily found great acceptance.

Even if we assume that every reason must, or at least can, attain to the conception of God, even without revelation, this clearly takes place only under the guidance of causality. This is so evident that it requires no proof. Therefore Chr. Wolf says (*Cosmologia Generalis, præf.*, p. 1): *Sane in theologia naturali existentiam Numinis e principiis cosmologicis demonstramus. Contingentia universi et ordinis naturæ, una cum impossibilitate casus, sunt scala, per quam a mundo hoc adspectabili ad Deum ascenditur.* And, before him, Leibnitz said, in connection with the law of causality: *Sans ce grand principe on ne saurait venir à la preuve de l'existence de Dieu*. On the other hand, the thought which is worked out in this chapter is so far from being essential and necessary to reason, that it is rather to be regarded as a veritable masterpiece of the monstrous productions of an age which, through strange circumstances, fell into the most singular aberrations and perversities, such as the age of the Scholastics was — an age which is unparalleled in the history of the world, and can never return again. This Scholasticism, as it advanced to its final form, certainly derived the principal proof of the existence of God from the conception of the *ens realissimum*, and only then used the other proofs as accessory. This, however, is mere methodology, and proves nothing as to the origin of theology in the human mind. Kant has here taken the procedure of Scholasticism for that of reason — a mistake which indeed he

has made more than once. If it were true that according to the essential laws of reason the Idea of God proceeds from the disjunctive syllogism under the form of an Idea of the most real being, this Idea would also have existed in the philosophy of antiquity; but of the *ens realissimum* there is nowhere a trace in any of the ancient philosophers, although some of them certainly teach that there is a Creator of the world, yet only as the giver of form to the matter which exists without him, δεμιουργος, a being whom they yet infer simply and solely in accordance with the law of causality. It is true that Sextus Empiricus (*adv. Math.*, ix. § 88) quotes an argument of Cleanthes, which some have held to be the ontological proof. This, however, it is not, but merely an inference from analogy; because experience teaches that upon earth one being is always better than another, and man, indeed, as the best, closes the series, but yet has many faults; therefore there must exist beings who are still better, and finally one being who is best of all (κρατιστον, αριστον), and this would be God.

On the detailed refutation of speculative theology which now follows I have only briefly to remark that it, and in general the whole criticism of the three so-called Ideas of reason, thus the whole Dialectic of Pure Reason, is indeed to a certain extent the goal and end of the whole work: yet this polemical part has not really an absolutely universal, permanent, and purely philosophical interest, such as is possessed by the preceding doctrinal part, *i.e.*, the æsthetic and analytic; but rather a temporary and local interest, because it stands in a special relation to the leading points of the philosophy which prevailed in Europe up till the time of Kant, the complete overthrow of which was yet, to his immortal credit, achieved by him through this polemic. He has eliminated theism from philosophy; for in it, as a science and not a system of faith, only that can find a place which is either empirically given or established by valid proofs. Naturally we only mean here the real seriously understood philosophy which is concerned with the truth, and nothing else; and by no means the jest of philosophy taught in the universities, in which, after Kant as before him, speculative theology plays the principal part, and where, also, after as before him, the soul appears without ceremony as a familiar person. For it is the philosophy endowed with salaries and fees, and, indeed, also with titles of Hofrath, which, looking proudly down from its height, remains for forty years entirely unaware of the existence of little people like me, and would be thoroughly

glad to be rid of the old Kant with his Critiques, that they might drink the health of Leibnitz with all their hearts. It is further to be remarked here, that as Kant was confessedly led to his doctrine of the *a priori* nature of the conception of causality by Hume's scepticism with regard to that conception, it may be that in the same way Kant's criticism of all speculative theology had its occasion in Hume's criticism of all popular theology, which he had given in his "Natural History of Religion," a book so well worth reading, and in the "Dialogues on Natural Religion." Indeed, it may be that Kant wished to a certain extent to supplement this. For the first-named work of Hume is really a critique of popular theology, the pitiable condition of which it seeks to show; while, on the other hand, it points to rational or speculative theology as the genuine, and that which is worthy of respect. But Kant now discloses the groundlessness of the latter, and leaves, on the other hand, popular theology untouched, nay, even establishes it in a nobler form as a faith based upon moral feeling. This was afterwards distorted by the philosophasters into rational apprehensions, consciousness of God, or intellectual intuitions of the supersensible, of the divine, &c., &c.; while Kant, as he demolished old and revered errors, and knew the danger of doing so, rather wished through the moral theology merely to substitute a few weak temporary supports, so that the ruin might not fall on him, but that he might have time to escape.

Now, as regards the performance of the task, no critique of reason was necessary for the refutation of the *ontological* proof of the existence of God; for without presupposing the æsthetic and analytic, it is quite easy to make clear that that ontological proof is nothing but a subtle playing with conceptions which is quite powerless to produce conviction. There is a chapter in the "*Organon*" of Aristotle which suffices as fully for the refutation of the ontological proof as if it had been written intentionally with that purpose. It is the seventh chapter of the second book of the "*Analyt. Post.*" Among other things, it is expressly said there: "το δε ειναι ουκ ουσια ουδενι," *i.e.*, *existentia nunquam ad essentiam rei pertinet*.

The refutation of the *cosmological* proof is an application to a given case of the doctrine of the Critique as expounded up to that point, and there is nothing to be said against it. The *physico-theological* proof is a mere amplification of the cosmological, which it presupposes, and it finds its full refutation only in the "Critique of Judgment." I refer the reader in this

connection to the rubric, "Comparative Anatomy," in my work on the Will in Nature.

In the criticism of this proof Kant has only to do, as we have already said, with speculative theology, and limits himself to the School. If, on the contrary, he had had life and popular theology also in view, he would have been obliged to add a fourth proof to the three he has considered — that proof which is really the effective one with the great mass of men, and which in Kant's technical language might best be called the *keraunological*. It is the proof which is founded upon the needy, impotent, and dependent condition of man as opposed to natural forces, which are infinitely superior, inscrutable, and for the most part threatening evil; to which is added man's natural inclination to personify everything, and finally the hope of effecting something by prayers and flattery, and even by gifts. In every human undertaking there is something which is not in our power and does not come within our calculations; the wish to win this for oneself is the origin of the gods. "*Primus in orbe Deos fecit timor*" is an old and true saying of Petronius. It is principally this proof which is criticised by Hume, who throughout appears as Kant's forerunner in the writings referred to above. But those whom Kant has placed in a position of permanent embarrassment by his criticism of speculative theology are the professors of philosophy. Salaried by Christian governments, they dare not give up the chief article of faith.[9] Now, how do these gentlemen help themselves? They simply declare that the existence of God is self-evident. Indeed! After the ancient world, at the expense of its conscience, had worked miracles to prove it, and the modern world, at the expense of its understanding, had brought into the field ontological, cosmological, and physico-theological proofs — to these gentlemen it is self-evident. And from this self-evident God they then explain the world: that is their philosophy.

Till Kant came there was a real dilemma between materialism and theism, *i.e.*, between the assumption that a blind chance, or that an intelligence working from without in accordance with purposes and conceptions, had brought about the world, *neque dabatur tertium*. Therefore atheism and materialism were the same; hence the doubt whether there really could be an atheist, *i.e.*, a man who really could attribute to blind chance the disposition of nature, so full of design, especially organised nature. See, for example, Bacon's Essays (*sermones fideles*), Essay 16, on Atheism. In the opinion of the great mass of men, and of the English, who

in such things belong entirely to the great mass (the mob), this is still the case, even with their most celebrated men of learning. One has only to look at Owen's "*Ostéologie Comparée*," of 1855, preface, p. 11, 12, where he stands always before the old dilemma between Democritus and Epicurus on the one side, and an intelligence on the other, in which *la connaissance d'un être tel que l'homme a existé avant que l'homme fit son apparition*. All design must have proceeded from an *intelligence*; he has never even dreamt of doubting this. Yet in the lecture based upon this now modified preface, delivered in the *Académie des Sciences* on the 5th September 1853, he says, with childish naivete: "*La téléologie, ou la théologie scientifique*" (*Comptes Rendus*, Sept. 1853), that is for him precisely the same thing! Is anything in nature designed? then it is a work of intention, of reflection, of intelligence. Yet, certainly, what has such an Englishman and the *Académie des Sciences* to do with the "Critique of Judgment," or, indeed, with my book upon the Will in Nature? These gentlemen do not see so far below them. These *illustres confrères* disdain metaphysics and the *philosophie allemande*: they confine themselves to the old woman's philosophy. The validity of that disjunctive major, that dilemma between materialism and theism, rests, however, upon the assumption that the present given world is the world of things in themselves; that consequently there is no other order of things than the empirical. But after the world and its order had through Kant become mere phenomenon, the laws of which rest principally upon the forms of our intellect, the existence and nature of things and of the world no longer required to be explained according to the analogy of the changes perceived or effected by us in the world; nor must that which we comprehend as means and end have necessarily arisen as the consequence of a similar knowledge. Thus, inasmuch as Kant, through his important distinction between phenomenon and thing in itself, withdrew the foundation from theism, he opened, on the other hand, the way to entirely different and more profound explanations of existence.

In the chapter on the ultimate aim of the natural dialectic of reason it is asserted that the three transcendent Ideas are of value as regulative principles for the advancement of the knowledge of nature. But Kant can barely have been serious in making this assertion. At least its opposite, that these assumptions are restrictive and fatal to all investigation of nature, is to every natural philosopher beyond doubt. To test this by an example, let any one consider whether the assumption of the soul as an immaterial, simple,

thinking substance would have been necessarily advantageous or in the highest degree impeding to the truths which Cabanis has so beautifully expounded, or to the discoveries of Flourens, Marshall Hall, and Ch. Bell. Indeed Kant himself says (*Prolegomena*, § 44), "The Ideas of the reason are opposed and hindering to the maxims of the rational knowledge of nature."

It is certainly not the least merit of Frederick the Great, that under his Government Kant could develop himself, and dared to publish the "Critique of Pure Reason." Hardly under any other Government would a salaried professor have ventured such a thing. Kant was obliged to promise the immediate successor of the great king that he would write no more.

I might consider that I could dispense with the criticism of the ethical part of the Kantian philosophy here because I have given a detailed and thorough criticism of it twenty-two years later than the present work in the "*Beiden Grundproblemen der Ethik*." However, what is here retained from the first edition, and for the sake of completeness must not be omitted, may serve as a suitable introduction to that later and much more thorough criticism, to which in the main I therefore refer the reader.

On account of Kant's love of architectonic symmetry, the theoretical reason had also to have a *pendant*. The *intellectus practicus* of the Scholastics, which again springs from the νους πρακτικος of Aristotle (*De Anima*, iii. 10, and *Polit.*, vii. c. 14: ὀ μεν γαρ πρακτικος εστι λογος, ὀ δε θεωρητικος), provides the word ready made. Yet here something quite different is denoted by it — not as there, the reason directed to technical skill. Here the practical reason appears as the source and origin of the undeniable ethical significance of human action, and of all virtue, all nobleness, and every attainable degree of holiness. All this accordingly should come from mere *reason*, and demand nothing but this. To act rationally and to act virtuously, nobly, holily, would be one and the same; and to act selfishly, wickedly, viciously, would be merely to act irrationally. However, all times and peoples and languages have distinguished the two, and held them to be quite different things; and so does every one even at the present day who knows nothing of the language of the new school, *i.e.*, the whole world, with the exception of a small company of German *savants*. Every one but these last understands by virtuous conduct and a rational course of life two entirely different things. To say that the sublime founder of the Christian religion, whose life is presented to us as the pattern of all

virtue, was *the most rational* of all men would be called a very unbecoming and even a blasphemous way of speaking; and almost as much so if it were said that His precepts contained all the best directions for a perfectly *rational life*. Further, that he who, in accordance with these precepts, instead of taking thought for his own future needs, always relieves the greater present wants of others, without further motive, nay, gives all his goods to the poor, in order then, destitute of all means of subsistence, to go and preach to others also the virtue which he practises himself; this every one rightly honours; but who ventures to extol it as the highest pitch of *reasonableness*? And finally, who praises it as a *rational* deed that Arnold von Winkelried, with surpassing courage, clasped the hostile spears against his own body in order to gain victory and deliverance for his countrymen? On the other hand, if we see a man who from his youth upwards deliberates with exceptional foresight how he may procure for himself an easy competence, the means for the support of wife and children, a good name among men, outward honour and distinction, and in doing so never allows himself to be led astray or induced to lose sight of his end by the charm of present pleasures or the satisfaction of defying the arrogance of the powerful, or the desire of revenging insults and undeserved humiliations he has suffered, or the attractions of useless aesthetic or philosophical occupations of the mind, or travels in interesting lands, but with great consistency works towards his one end, — who ventures to deny that such a philistine is in quite an extraordinary degree *rational*, even if he has made use of some means which are not praiseworthy but are yet without danger? Nay, more, if a bad man, with deliberate shrewdness, through a well-thought-out plan attains to riches and honours, and even to thrones and crowns, and then with the acutest cunning gets the better of neighbouring states, overcomes them one by one, and now becomes a conqueror of the world, and in doing so is not led astray by any respect for right, any sense of humanity, but with sharp consistency tramples down and dashes to pieces everything that opposes his plan, without compassion plunges millions into misery of every kind, condemns millions to bleed and die, yet royally rewards and always protects his adherents and helpers, never forgetting anything, and thus reaches his end, — who does not see that such a man must go to work in a most rational manner? — that, as a powerful understanding was needed to form the plans, their execution demanded the complete command of the *reason*, and indeed properly of *practical reason*?

Or are the precepts which the prudent and consistent, the thoughtful and far-seeing Machiavelli prescribes to the prince *irrational*?[10]

As wickedness is quite consistent with reason, and indeed only becomes really terrible in this conjunction, so, conversely, nobleness is sometimes joined with want of reason. To this may be attributed the action of Coriolanus, who, after he had applied all his strength for years to the accomplishment of his revenge upon the Romans, when at length the time came, allowed himself to be softened by the prayers of the Senate and the tears of his mother and wife, gave up the revenge he had so long and so painfully prepared, and indeed, by thus bringing on himself the just anger of the Volscians, died for those very Romans whose thanklessness he knew and desired so intensely to punish. Finally, for the sake of completeness, it may be mentioned that reason may very well exist along with want of understanding. This is the case when a foolish maxim is chosen, but is followed out consistently. An example of this is afforded by the case of the Princess Isabella, daughter of Philip II., who vowed that she would not put on a clean chemise so long as Ostend remained unconquered, and kept her word through three years. In general all vows are of this class, whose origin is a want of insight as regards the law of causality, *i.e.*, want of understanding; nevertheless it is rational to fulfil them if one is of such narrow understanding as to make them.

In agreement with what we have said, we see the writers who appeared just before Kant place the conscience, as the seat of the moral impulses, in opposition to the reason. Thus Rousseau, in the fourth book of "*Emile*," says: "*La raison nous trompe, mais la conscience ne trompe jamais*;" and further on: "*Il est impossible d'expliquer par les conséquences de notre nature le principe immédiat de la conscience indépendant de la raison même*." Still further: "*Mes sentimens naturels parlaient pour l'intérêt commun, ma raison rapportait tout a moi.... On a beau vouloir etablir la vertu par la raison seul, quelle solide base peut-on lui donner*?" In the "*Rêveries du Promeneur*," prom. 4 ême, he says: "*Dans toutes les questions de morale difficiles je me suis tojours bien trouvé de les résoudre par le dictamen de la conscience, plutôt que par les lumières de la raison*." Indeed Aristotle already says expressly (*Eth. Magna*, i. 5) that the virtues have their seat in the αλογῳ μοριῳ της ψυχης (*in parte irrationali animi*), and not in

the λογον εχοντι (*in parte rationali*). In accordance with this, Stobæus says (Ecl., ii, c.7), speaking of the Peripatetics: "Την ηθικην αρετην ὑπολαμβανουσι περι το αλογον μερος γιγνεσθαι της ψυχης, επειδη διμερη προς την παρουσαν θεωριαν ὑπεθεντο την ψυχην, το μεν λογικον εχουσαν, το δ᾽ αλογον. Και περι μεν το λογικον την καλοκαγαθιαν γιγνεσθαν, και την φρονησιν, και την αγχινοιαν, και σοφιαν, και ευμαθειαν, και μνημην, και τας ὁμοιους; περι δε το αλογον, σωφροσυνην, και δικαιοσυνην, και ανδρειαν, και τας αλλας τας ηθικας καλουμενας αρετας." (*Ethicam virtutem circa partem animæ ratione carentem versari putant, cam duplicem, ad hanc disquisitionem, animam ponant, ratione prœditam, et ea carentem. In parte vero ratione prœdita collocant ingenuitatem, prudentiam, perspicacitatem, sapientiam, docilitatem, memoriam et reliqua; in parte vero ratione destituta temperantiam, justitiam, fortitadinem, et reliquas virtutes, quas ethicas vocant.*) And Cicero (*De Nat. Deor.*, iii., c. 26-31) explains at length that reason is the necessary means, the tool, of all crime.

I have explained *reason* to be the *faculty of framing concepts*. It is this quite special class of general non-perceptible ideas, which are symbolised and fixed only by words, that distinguishes man from the brutes and gives him the pre-eminence upon earth. While the brute is the slave of the present, and knows only immediate sensible motives, and therefore when they present themselves to it is necessarily attracted or repelled by them, as iron is by the magnet, in man, on the contrary, deliberation has been introduced through the gift of reason.

This enables him easily to survey as a whole his life and the course of the world, looking before and after; it makes him independent of the present, enables him to go to work deliberately, systematically, and with foresight, to do evil as well as to do good. But what he does he does with complete self-consciousness; he knows exactly how his will decides, what in each case he chooses, and what other choice was in the nature of the case possible; and from this self-conscious willing he comes to know himself and mirrors himself in his actions. In all these relations to the conduct of men reason is to be called *practical*; it is only theoretical so far as the objects with which it is concerned have no relation to the action of the thinker, but have purely a theoretical interest, which very few men are capable of feeling. What in this sense is called *practical reason* is very

nearly what is signified by the Latin word *prudentia*, which, according to Cicero (*De Nat. Deor.* ii., 22), is a contraction of *providentia*; while, on the other hand, *ratio*, if used of a faculty of the mind, signifies for the most part theoretical reason proper, though the ancients did not observe the distinction strictly. In nearly all men reason has an almost exclusively practical tendency; but if this also is abandoned thought loses the control of action, so that it is then said, "*Scio meliora, proboque, deteriora sequor*," or "*Le matin je fais des projets, et le soir je fais des sottises*." Thus the man does not allow his conduct to be guided by his thought, but by the impression of the moment, after the manner of the brute; and so he is called irrational (without thereby imputing to him moral turpitude), although he is not really wanting in reason, but in the power of applying it to his action; and one might to a certain extent say his reason is theoretical and not practical. He may at the same time be a really good man, like many a one who can never see any one in misfortune without helping him, even making sacrifices to do so, and yet leaves his debts unpaid. Such an irrational character is quite incapable of committing great crimes, because the systematic planning, the discrimination and self-control, which this always requires are quite impossible to him. Yet, on the other hand, he will hardly attain to a very high degree of virtue, for, however much inclined to good he may be by nature, those single vicious and wicked emotions to which every one is subject cannot be wanting; and where reason does not manifest itself practically, and oppose to them unalterable maxims and firm principles, they must become deeds.

Finally, *reason* manifests itself very specially as *practical* in those exceedingly rational characters who on this account are called in ordinary life practical philosophers, and who are distinguished by an unusual equanimity in disagreeable as in pleasing circumstances, an equable disposition, and a determined perseverance in resolves once made. In fact, it is the predominance of reason in them, *i.e.*, the more abstract than intuitive knowledge, and therefore the survey of life by means of conceptions, in general and as a whole, which has enabled them once for all to recognise the deception of the momentary impression, the fleeting nature of all things, the shortness of life, the emptiness of pleasures, the fickleness of fortune, and the great and little tricks of chance. Therefore nothing comes to them unexpectedly, and what they know in the abstract does not surprise nor disturb them when it meets them in the actual and in the particular case,

though it does so in the case of those less reasonable characters upon whom the present, the perceptible, the actual, exerts such an influence that the cold, colourless conceptions are thrown quite into the background of consciousness, and forgetting principles and maxims, they are abandoned to emotions and passions of every kind. I have already explained at the end of the first book that in my opinion the ethics of Stoicism were simply a guide to a truly reasonable life, in this sense. Such a life is also repeatedly praised by Horace in very many passages. This is the significance of his *nil admirari*, and also of the Delphic Μηδεν αγαν. To translate *nil admirari* "to admire nothing" is quite wrong. This Horatian maxim does not concern the theoretical so much as the practical, and its real meaning is: "Prize no object unconditionally. Do not fall in love with anything; do not believe that the possession of anything can give you happiness. Every intense longing for an object is only a delusive chimera, which one may just as well, and much more easily, get quit of by fuller knowledge as by attained possession." Cicero also uses *admirari* in this sense (*De Divinatione*, ii. 2). What Horace means is thus the αθαμβια and ακαταπληξις, also αθαυμασια, which Democritus before him prized as the highest good (see *Clem. Alex. Strom.*, ii. 21, and cf. *Strabo*, i. p. 98 and 105). Such reasonableness of conduct has properly nothing to do with virtue and vice; but this practical use of reason is what gives man his pre-eminence over the brute, and only in this sense has it any meaning and is it permissible to speak of a dignity of man.

In all the cases given, and indeed in all conceivable cases, the distinction between rational and irrational action runs back to the question whether the motives are abstract conceptions or ideas of perception. Therefore the explanation which I have given of reason agrees exactly with the use of language at all times and among all peoples — a circumstance which will not be regarded as merely accidental or arbitrary, but will be seen to arise from the distinction of which every man is conscious, of the different faculties of the mind, in accordance with which consciousness he speaks, though certainly he does not raise it to the distinctness of an abstract definition. Our ancestors did not make the words without attaching to them a definite meaning, in order, perhaps, that they might lie ready for philosophers who might possibly come centuries after and determine what ought to be thought in connection with them; but they denoted by them quite definite conceptions. Thus the words are no longer unclaimed, and to attribute to them an entirely different sense from that which they have

hitherto had means to misuse them, means to introduce a licence in accordance with which every one might use any word in any sense he chose, and thus endless confusion would necessarily arise. Locke has already shown at length that most disagreements in philosophy arise from a false use of words. For the sake of illustration just glance for a moment at the shameful misuse which philosophers destitute of thoughts make at the present day of the words substance, consciousness, truth, and many others. Moreover, the utterances and explanations concerning reason of all philosophers of all ages, with the exception of the most modern, agree no less with my explanation of it than the conceptions which prevail among all nations of that prerogative of man. Observe what Plato, in the fourth book of the Republic, and in innumerable scattered passages, calls the λογιμον, or λογιστικον της ψυχης, what Cicero says (*De Nat. Deor.*, iii. 26-31), what Leibnitz and Locke say upon this in the passages already quoted in the first book. There would be no end to the quotations here if one sought to show how all philosophers before Kant have spoken of reason in general in my sense, although they did not know how to explain its nature with complete definiteness and distinctness by reducing it to one point. What was understood by reason shortly before Kant's appearance is shown in general by two essays of Sulzer in the first volume of his miscellaneous philosophical writings, the one entitled "Analysis of the Conception of Reason," the other, "On the Reciprocal Influence of Reason and Language." If, on the other hand, we read how reason is spoken about in the most recent times, through the influence of the Kantian error, which after him increased like an avalanche, we are obliged to assume that the whole of the wise men of antiquity, and also all philosophers before Kant, had absolutely no reason at all; for the immediate perceptions, intuitions, apprehensions, presentiments of the reason now discovered were as utterly unknown to them as the sixth sense of the bat is to us. And as far as I am concerned, I must confess that I also, in my weakness, cannot comprehend or imagine that reason which directly perceives or apprehends, or has an intellectual intuition of the super-sensible, the absolute, together with long yarns that accompany it, in any other way than as the sixth sense of the bat. This, however, must be said in favour of the invention or discovery of such a reason, which at once directly perceives whatever you choose, that it is an incomparable expedient for withdrawing oneself from the affair in the easiest manner in the world, along with one's favourite ideas, in spite of all

Kants, with their Critiques of Reason. The invention and the reception it has met with do honour to the age.

Thus, although what is essential in reason (το λογιμον, ἠ φρονησις, *ratio*, *raison*, Vernunft) was, on the whole and in general, rightly understood by all philosophers of all ages, though not sharply enough defined nor reduced to one point, yet it was not so clear to them what the understanding (νους, διανοια, *intellectus*, *esprit*, Verstand) is. Therefore they often confuse it with reason, and just on this account they did not attain to a thoroughly complete, pure, and simple explanation of the nature of the latter. With the Christian philosophers the conception of reason received an entirely extraneous, subsidiary meaning through the opposition of it to revelation. Starting, then, from this, many are justly of opinion that the knowledge of the duty of virtue is possible from mere reason, *i.e.*, without revelation. Indeed this aspect of the matter certainly had influence upon Kant's exposition and language. But this opposition is properly of positive, historical significance, and is therefore for philosophy a foreign element, from which it must keep itself free.

We might have expected that in his critiques of theoretical and practical reason Kant would have started with an exposition of the nature of reason in general, and, after he had thus defined the *genus*, would have gone on to the explanation of the two *species*, showing how one and the same reason manifests itself in two such different ways, and yet, by retaining its principal characteristic, proves itself to be the same. But we find nothing of all this. I have already shown how inadequate, vacillating, and inconsistent are the explanations of the faculty he is criticising, which he gives here and there by the way in the "Critique of Pure Reason." The *practical* reason appears in the "Critique of Pure Reason" without any introduction, and afterwards stands in the "Critique" specially devoted to itself as something already established. No further account of it is given, and the use of language of all times and peoples, which is treated with contempt, and the definitions of the conception given by the greatest of earlier philosophers, dare not lift up their voices. In general, we may conclude from particular passages that Kant's opinion amounts to this: the knowledge of principles *a priori* is the essential characteristic of reason: since now the knowledge of the ethical significance of action is not of empirical origin, it also is an *a priori* principle, and accordingly proceeds from the reason, and therefore thus far the reason is *practical*. I have already spoken enough of the

incorrectness of this explanation of reason. But, independently of this, how superficial it is, and what a want of thoroughness it shows, to make use here of the single quality of being independent of experience in order to combine the most heterogeneous things, while overlooking their most essential and immeasurable difference in other respects. For, even assuming, though we do not admit it, that the knowledge of the ethical significance of action springs from an imperative lying in us, an unconditioned *ought*, yet how fundamentally different would such an imperative be from those universal *forms of knowledge* of which, in the "Critique of Pure Reason," Kant proves that we are conscious *a priori*, and by virtue of which consciousness we can assert beforehand an unconditioned *must*, valid for all experience possible for us. But the difference between this *must*, this necessary form of all objects which is already determined in the subject, and that *ought* of morality is so infinitely great and palpable that the mere fact that they agree in the one particular that neither of them is empirically known may indeed be made use of for the purpose of a witty comparison, but not as a philosophical justification for regarding their origin as the same.

Moreover, the birthplace of this child of practical reason, the *absolute ought* or the categorical imperative, is not in the "Critique of Practical Reason," but in that of "Pure Reason," p. 802; V. 830. The birth is violent, and is only accomplished by means of the forceps of a *therefore*, which stands boldly and audaciously, indeed one might say shamelessly, between two propositions which are utterly foreign to each other and have no connection, in order to combine them as reason and consequent. Thus, that not merely perceptible but also abstract motives determine us, is the proposition from which Kant starts, expressing it in the following manner: "Not merely what excites, *i.e.*, what affects the senses directly, determines human will, but we have a power of overcoming the impressions made upon our sensuous appetitive faculty through ideas of that which is itself in a more remote manner useful or hurtful. These deliberations as to what is worthy of desire, with reference to our whole condition, *i.e.*, as to what is good and useful, rest upon reason." (Perfectly right; would that he only always spoke so rationally of reason!) "Reason *therefore* gives! also laws, which are imperatives, *i.e.*, objective laws of freedom, and say what ought to take place, though perhaps it never does take place"! Thus, without further authentication, the categorical imperative comes into the world, in

order to rule there with its unconditioned *ought* — a sceptre of wooden iron. For in the conception "*ought*" there lies always and essentially the reference to threatened punishment, or promised reward, as a necessary condition, and cannot be separated from it without abolishing the conception itself and taking all meaning from it. Therefore an *unconditioned ought* is a *contradictio in adjecto*. It was necessary to censure this mistake, closely as it is otherwise connected with Kant's great service to ethics, which consists in this, that he has freed ethics from all principles of the world of experience, that is, from all direct or indirect doctrines of happiness, and has shown in a quite special manner that the kingdom of virtue is not of this world. This service is all the greater because all ancient philosophers, with the single exception of Plato, thus the Peripatetics, the Stoics, and the Epicureans, sought by very different devices either to make virtue and happiness dependent on each other in accordance with the principle of sufficient reason, or to identify them in accordance with the principle of contradiction. This charge applies with equal force to all modern philosophers down to Kant. His merit in this respect is therefore very great; yet justice demands that we should also remember here first that his exposition and elaboration often does not correspond with the tendency and spirit of his ethics, and secondly that, even so, he is not really the first who separated virtue from all principles of happiness. For Plato, especially in the "Republic," the principal tendency of which is just this, expressly teaches that virtue is to be chosen for itself alone, even if unhappiness and ignominy are inevitably connected with it. Still more, however, Christianity preaches a perfectly unselfish virtue, which is practised not on account of the reward in a life after death, but quite disinterestedly from love to God, for works do not justify, but only faith, which accompanies virtue, so to speak, as its symptom, and therefore appears quite irrespective of reward and of its own accord. See Luther's "*De Libertate Christiana*." I will not take into account at all the Indians, in whose sacred books the hope of a reward for our works is everywhere described as the way of darkness, which can never lead to blessedness. Kant's doctrine of virtue, however, we do not find so pure; or rather the exposition remains far behind the spirit of it, and indeed falls into inconsistency. In his *highest good*, which he afterwards discussed, we find virtue united to happiness. The ought originally so unconditioned does yet afterwards postulate one condition, in order to escape from the inner contradiction with which it is affected and with which it cannot live.

Happiness in the highest good is not indeed really meant to be the motive for virtue; yet there it is, like a secret article, the existence of which reduces all the rest to a mere sham contract. It is not really the reward of virtue, but yet it is a voluntary gift for which virtue, after work accomplished, stealthily opens the hand. One may convince oneself of this from the "Critique of Practical Reason" (p. 223-266 of the fourth, or p. 264-295 of Rosenkranz's, edition). The whole of Kant's moral theology has also the same tendency, and just on this account morality really destroys itself through moral theology. For I repeat that all virtue which in any way is practised for the sake of a reward is based upon a prudent, methodical, far-seeing egoism.

The content of the absolute ought, the fundamental principle of the practical reason, is the famous: "So act that the maxim of your will might always be also valid as the principle of a universal legislation." This principle presents to him who desires a rule for his own will the task of seeking such a rule for the wills of all. Then the question arises how such a rule is to be found. Clearly, in order to discover the rule of my conduct, I ought not to have regard to myself alone, but to the sum of all individuals. Then, instead of my own well-being, the well-being of all without distinction becomes my aim. Yet the aim still always remains well-being. I find, then, that all can be equally well off only if each limits his own egoism by that of others. From this it certainly follows that I must injure no one, because, since this principle is assumed to be universal, I also will not be injured. This, however, is the sole ground on account of which I, who do not yet possess a moral principle, but am only seeking one, can wish this to be a universal law. But clearly in this way the desire of well-being, *i.e.*, egoism, remains the source of this ethical principle. As the basis of politics it would be excellent, as the basis of ethics it is worthless. For he who seeks to establish a rule for the wills of all, as is demanded by that moral principle, necessarily stands in need of a rule himself; otherwise everything would be alike to him. But this rule can only be his own egoism, since it is only this that is affected by the conduct of others; and therefore it is only by means of this egoism, and with reference to it, that each one can have a will concerning the conduct of others, and that it is not a matter of indifference to him. Kant himself very naively intimates this (p. 123 of the "Critique of Practical Reason;" Rosenkranz's edition, p. 192), where he thus prosecutes the search for maxims for the will: "If every one regarded the need of others

with complete indifference, *and thou also didst belong* to such an order of things, wouldst thou consent thereto?" *Quam temere in nosmet legem sancimus iniquam!* would be the rule of the consent inquired after. So also in the "Fundamental Principles of the Metaphysic of Morals" (p. 56 of the third, and p. 50 of Rosenkranz's, edition): "A will which resolved to assist no one in distress would contradict itself, for cases might arise in which *it required the love and sympathy of others*," &c. &c. This principle of ethics, which when light is thrown upon it is therefore nothing else than an indirect and disguised expression of the old, simple principle, "*Quod tibi fieri non vis, alteri ne feceris*," is related first and directly to passivity, suffering, and then only by means of this to action. Therefore, as we have said, it would be thoroughly serviceable as a guide for the constitution of the State, which aims at the prevention of *the suffering of wrong*, and also desires to procure for all and each the greatest sum of well-being. But in ethics, where the object of investigation is *action* as *action*, and in its direct significance for the *actor* — not its consequences, suffering, or its relation to others — in this reference, I say, it is altogether inadmissible, because at bottom it really amounts to a principle of happiness, thus to egoism.

We cannot, therefore, share Kant's satisfaction that his principle of ethics is not a material one, *i.e.*, one which sets up an object as a motive, but merely formal, whereby it corresponds symmetrically to the formal laws with which the "Critique of Pure Reason" has made us familiar. Certainly it is, instead of a law, merely a formula for finding such a law. But, in the first place, we had this formula already more briefly and clearly in the "*Quod tibi fieri non vis, alteri ne feceris*;" and, secondly, the analysis of this formula shows that it is simply and solely the reference to one's own happiness that gives it content, and therefore it can only be serviceable to a rational egoism, to which also every legal constitution owes its origin.

Another mistake which, because it offends the feelings of every one, has often been condemned, and was satirised by Schiller in an epigram, is the pedantic rule that for an act to be really good and meritorious it must be done simply and solely out of respect for the known law and the conception of duty, and in accordance with a maxim known to the reason *in abstracto*, and not from any inclination, not from benevolence felt towards others, not from tender-hearted compassion, sympathy, or emotion of the heart, which (according to the "Critique of Practical Reason," p. 213; Rosenkranz's

edition, p. 257) to right-thinking persons are indeed very burdensome, as confusing their deliberate maxims. The act must be performed unwillingly and with self-compulsion. Remember that nevertheless the hope of reward is not allowed to enter, and estimate the great absurdity of the demand. But, what is saying more, this is directly opposed to the true spirit of virtue; not the act, but the willingness to do it, the love from which it proceeds, and without which it is a dead work, constitutes its merit. Therefore Christianity rightly teaches that all outward works are worthless if they do not proceed from that genuine disposition which consists in true goodwill and pure love, and that what makes blessed and saves is not the works done (*opera operata*), but the faith, the genuine disposition, which is the gift of the Holy Ghost alone, and which the free, deliberative will, having only the law in view, does not produce. This demand of Kant's, that all virtuous conduct shall proceed from pure, deliberate respect for the law and in accordance with its abstract maxims, coldly and without inclination, nay, opposed to all inclination, is just the same thing as if he asserted that every work of art must be accomplished by a well-considered application of æsthetical rules. The one is just as perverse as the other. The question, already handled by Plato and Seneca, whether virtue can be taught, is to be answered in the negative. We must finally make up our minds to see, what indeed was the source of the Christian doctrine of election by grace, that as regards its chief characteristic and its inner nature, virtue, like genius, is to a certain extent inborn; and that just as little as all the professors of æsthetics could impart to any one the power of producing works of genius, *i.e.*, genuine works of art, so little could all the professors of ethics and preachers of virtue transform an ignoble into a virtuous and noble character, the impossibility of which is very much more apparent than that of turning lead into gold. The search for a system of ethics and a first principle of the same, which would have practical influence and would actually transform and better the human race, is just like the search for the philosopher's stone. Yet I have spoken at length at the end of the fourth book of the possibility of an entire change of mind or conversion of man (new birth), not by means of abstract (ethics) but of intuitive knowledge (the work of grace). The contents of that book relieve me generally of the necessity of dwelling longer upon this point.

That Kant by no means penetrated to the real significance of the ethical content of actions is shown finally by his doctrine of the highest good as the

necessary combination of virtue and happiness, a combination indeed in which virtue would be that which merits happiness. He is here involved in the logical fallacy that the conception of merit, which is here the measure or test, already presupposes a theory of ethics as its own measure, and thus could not be deducible from it. It appeared in our fourth book that all genuine virtue, after it has attained to its highest grade, at last leads to a complete renunciation in which all willing finds an end. Happiness, on the other hand, is a satisfied wish; thus the two are essentially incapable of being combined. He who has been enlightened by my exposition requires no further explanation of the complete perverseness of this Kantian view of the highest good. And, independent of my positive exposition, I have no further negative exposition to give.

Kant's love of architectonic symmetry meets us also in the "Critique of Practical Reason," for he has given it the shape of the "Critique of Pure Reason," and has again introduced the same titles and forms with manifest intention, which becomes specially apparent in the table of the categories of freedom.

The "Philosophy of Law" is one of Kant's latest works, and is so poor that, although I entirely disagree with it, I think a polemic against it is superfluous, since of its own weakness it must die a natural death, just as if it were not the work of this great man, but the production of an ordinary mortal. Therefore, as regards the "Philosophy of Law," I give up the negative mode of procedure and refer to the positive, that is, to the short outline of it given in the fourth book. Just one or two general remarks on Kant's "Philosophy of Law" may be made here. The errors which I have condemned in considering the "Critique of Pure Reason," as clinging to Kant throughout, appear in the "Philosophy of Law" in such excess that one often believes he is reading a satirical parody of the Kantian style, or at least that he is listening to a Kantian. Two principal errors, however, are these. He desires (and many have since then desired) to separate the Philosophy of Law sharply from ethics, and yet not to make the former dependent upon positive legislation, *i.e.*, upon arbitrary sanction, but to let the conception of law exist for itself pure and *a priori*. But this is not possible; because conduct, apart from its ethical significance, and apart from the physical relation to others, and thereby from external sanction, does not admit even of the possibility of any third view. Consequently,

when he says, "Legal obligation is that which *can* be enforced," this *can* is either to be understood physically, and then all law is positive and arbitrary, and again all arbitrariness that achieves its end is law; or the *can* is to be understood ethically, and we are again in the province of ethics. With Kant the conception of legal right hovers between heaven and earth, and has no ground on which to stand; with me it belongs to ethics. Secondly, his definition of the conception law is entirely negative, and thereby inadequate.[11] Legal right is that which is consistent with the compatibility of the respective freedom of individuals together, according to a general law. Freedom (here the empirical, *i.e.*, physical, not the moral freedom of the will) signifies not being hindered or interfered with, and is thus a mere negation; compatibility, again, has exactly the same significance. Thus we remain with mere negations and obtain no positive conception, indeed do not learn at all, what is really being spoken about, unless we know it already from some other source. In the course of the exposition the most perverse views afterwards develop themselves, such as that in the state of nature, *i.e.*, outside the State, there is no right to property at all, which really means that all right or law is positive, and involves that natural law is based upon positive law, instead of which the case ought to be reversed. Further, the founding of legal acquisition on possession; the ethical obligation to establish the civil constitution; the ground of the right of punishment, &c., &c., all of which, as I have said, I do not regard as worth a special refutation. However, these Kantian errors have exercised a very injurious influence. They have confused and obscured truths long known and expressed, and have occasioned strange theories and much writing and controversy. This certainly cannot last, and we see already how truth and sound reason again make way for themselves. Of the latter, the "*Naturrecht*" of J. C. F. Meister specially bears evidence, and is thus a contrast to many a preposterous theory, though I do not regard it as on this account a pattern of perfection.

On the "Critique of Judgment" also, after what has been said, I must be very short. We cannot but be surprised that Kant, to whom art certainly was very foreign, and who to all appearance had little susceptibility for the beautiful, indeed probably never had the opportunity of seeing an important work of art, and who seems, finally, to have had no knowledge of Goethe, the only man of his century and nation who was fit to be placed by his side

as his giant equal, — it is, I say, surprising how, notwithstanding all this, Kant was able to render a great and permanent service to the philosophical consideration of art and the beautiful. His merit lies in this, that much as men had reflected upon the beautiful and upon art, they had yet really always considered it only from the empirical point of view, and had investigated upon a basis of facts what quality distinguished the object of any kind which was called beautiful from other objects of the same kind. On this path they first arrived at quite special principles, and then at more general ones. They sought to separate true artistic beauty from false, and to discover marks of this genuineness, which could then serve again as rules. What gives pleasure as beautiful and what does not, what therefore is to be imitated, what is to be striven against, what is to be avoided, what rules, at least negative rules, are to be established, in short, what are the means of exciting æsthetic satisfaction, *i.e.*, what are the conditions of this residing in the object — this was almost exclusively the theme of all treatises upon art. This path was followed by Aristotle, and in the most recent times we find it chosen by Home, Burke, Winckelmann, Lessing, Herder, and many others. It is true that the universality of the æsthetical principles discovered finally led back to the subject, and it was observed that if the effect upon the subject were adequately known we would then also be able to determine *a priori* the causes of this which lie in the object, and thus alone this method of treatment could attain to the certainty of a science. This occasioned once and again psychological disquisitions. Specially however, Alexander Baumgarten produced with this intention a general æsthetic of all beauty, in which he started from the conception of the perfection of sensuous knowledge, that is, of knowledge of perception. With him also, however, the subjective part is done with as soon as this conception has been established, and he passes on to the objective part and to the practical, which is connected with it. But here also the merit was reserved for Kant of investigating seriously and profoundly *the feeling itself*, in consequence of which we call the object occasioning it beautiful, in order to discover, wherever it was possible, the constituent elements and conditions of it in our nature. His investigation, therefore, took an entirely subjective direction. This path was clearly the right one, for in order to explain a phenomenon which is given in its effects, one must know accurately this effect itself, if one is to determine thoroughly the nature of the cause. Yet Kant's merit in this regard does not really extend much further than this,

that he has indicated the right path, and by a provisional attempt has given an example of how, more or less, it is to be followed. For what he gave cannot be regarded as objective truth and as a real gain. He gave the method for this investigation, he broke ground in the right direction, but otherwise he missed the mark.

In the "Critique of Æsthetical Judgment" the observation first of all forces itself upon us that Kant retains the method which is peculiar to his whole philosophy, and which I have considered at length above — I mean the method of starting from abstract knowledge in order to establish knowledge of perception, so that the former serves him, so to speak, as a *camera obscura* in which to receive and survey the latter. As in the "Critique of Pure Reason" the forms of judgment are supposed to unfold to him the knowledge of our whole world of perception, so in this "Critique of Æsthetical Judgment" he does not start from the beautiful itself, from the perceptible and immediately beautiful, but from the *judgment* of the beautiful, the so-called, and very badly so-called, judgment of taste. This is his problem. His attention is especially aroused by the circumstance that such a judgment is clearly the expression of something that takes place in the subject, but yet is just as universally valid as if it concerned a quality of the object. It is this that struck him, not the beautiful itself. He starts always merely from the assertions of others, from the judgment of the beautiful, not from the beautiful itself. It is therefore as if he knew it simply from hearsay, not directly. A blind man of high understanding could almost in the same way make up a theory of colours from very accurate reports which he had heard concerning them. And really we can only venture to regard Kant's philosophemes concerning the beautiful as in almost the same position. Then we shall find that his theory is very ingenious indeed, that here and there telling and true observations are made; but his real solution of the problem is so very insufficient, remains so far below the dignity of the subject, that it can never occur to us to accept it as objective truth. Therefore I consider myself relieved from the necessity of refuting it; and here also I refer to the positive part of my work.

With regard to the form of his whole book, it is to be observed that it originated in the idea of finding in the teleological conception the key to the problem of the beautiful. This inspiration is deduced, which is always a matter of no difficulty, as we have learnt from Kant's successors. Thus there now arises the strange combination of the knowledge of the beautiful with

that of the teleology of natural bodies in *one* faculty of knowledge called *judgment*, and the treatment of these two heterogeneous subjects in one book. With these three powers of knowledge, reason, judgment, and understanding, a variety of symmetrical-architectonic amusements are afterwards undertaken, the general inclination to which shows itself in many ways in this book; for example, in the forcible adaptation of the whole of it to the pattern of the "Critique of Pure Reason," and very specially in the antinomy of the æsthetical judgment, which is dragged in by the hair. One might also extract a charge of great inconsistency from the fact that after it has been incessantly repeated in the "Critique of Pure Reason" that the understanding is the faculty of judgment, and after the forms of its judgment have been made the foundation-stone of all philosophy, a quite special faculty of judgment now appears, which is completely different from the former. For the rest, what I call the faculty of judgment, the capacity for translating knowledge of perception into abstract knowledge, and again of applying the latter correctly to the former, is explained in the positive part of my work.

By far the best part of the "Critique of Æsthetical Judgment" is the theory of the sublime. It is incomparably more successful than that of the beautiful, and does not only give, as that does, the general method of investigation, but also a part of the right way to it — so much so that even though it does not give the real solution of the problem, it yet touches very closely upon it.

In the "Critique of the Teleological Judgment," on account of the simplicity of the matter, we can recognise perhaps more than anywhere else Kant's rare talent of turning a thought this way and that way, and expressing it in a multitude of different ways, until out of it there grows a book. The whole book is intended to say this alone: although organised bodies necessarily appear to us as if they were constructed in accordance with a conceived design of an end which preceded them, yet we are not justified in assuming that this is objectively the case. For our intellect, to which things are given from without and indirectly, which thus never knows their inner nature through which they arise and exist, but merely their outward side, cannot otherwise comprehend a certain quality peculiar to organised productions of nature than by analogy, for it compares it with the intentionally accomplished works of man, the nature of which is determined by a design and the conception of this design. This analogy is sufficient to

enable us to comprehend the agreement of all the parts with the whole, and thus indeed to give us the clue to their investigation; but it must by no means on this account be made the actual ground of explanation of the origin and existence of such bodies. For the necessity of so conceiving them is of subjective origin. Somewhat in this way I would epitomise Kant's doctrine on this question. In its most important aspect he had expounded it already in the "Critique of Pure Reason," p. 692-702; V., 720-730. But in the knowledge of *this* truth also we find David Hume to be Kant's worthy forerunner. He also had keenly controverted that assumption in the second part of his "Dialogues concerning Natural Religion." The difference between Hume's criticism of that assumption and Kant's is principally this, that Hume criticised it as an assumption based upon experience, while Kant, on the other hand, criticised it as an *a priori* assumption. Both are right, and their expositions supplement each other. Indeed what is really essential in the Kantian doctrine on this point we find already expressed in the commentary of Simplicius on Aristotle's Physics: "ἡ δε πλανη γεγονεν αυτοις απο του ἡγεισθαι, παντα τα ἑνεκα του γινομενα κατα προαιρεσιν γενεσθαι και λογισμον, τα δε φυσει μη ὁυτως ὁραν γινομενα." (*Error iis ortus est ex eo, quod credebant, omnia, quæ propter finem aliquem fierent, ex proposito et ratiocinio fieri, dum videbant, naturæ opera non ita fieri.*) *Schol. in Arist., ex edit. Berol.*, p. 354. Kant is perfectly right in the matter; and it was necessary that after it had been shown that the conception of cause and effect is inapplicable to the whole of nature in general, in respect of its existence, it should also be shown that in respect of its qualities it is not to be thought of as the effect of a cause guided by motives (designs). If we consider the great plausibility of the physico-theological proof, which even Voltaire held to be irrefragable, it was clearly of the greatest importance to show that what is subjective in our comprehension, to which Kant had relegated space, time, and causality, extends also to our judgment of natural bodies; and accordingly the compulsion which we feel to think of them as having arisen as the result of premeditation, according to designs, thus in such a way that *the idea of them preceded their existence*, is just as much of subjective origin as the perception of space, which presents itself so objectively, and that therefore it must not be set up as objective truth. Kant's exposition of the matter, apart from its tedious prolixity and repetitions, is excellent. He rightly asserts that we can never succeed in explaining the nature of organised bodies from merely mechanical causes,

by which he understands the undesigned and regular effect of all the universal forces of nature. Yet I find here another flaw. He denies the possibility of such an explanation merely with regard to the teleology and apparent adaptation of *organised* bodies. But we find that even where there is no organisation the grounds of explanation which apply to *one* province of nature cannot be transferred to another, but forsake us as soon as we enter a new province, and new fundamental laws appear instead of them, the explanation of which is by no means to be expected from the laws of the former province. Thus in the province of the mechanical, properly so called, the laws of gravitation, cohesion, rigidity, fluidity, and elasticity prevail, which in themselves (apart from my explanation of all natural forces as lower grades of the objectification of will) exist as manifestations of forces which cannot be further explained, but themselves constitute the principles of all further explanation, which merely consists in reduction to them. If we leave this province and come to the phenomena of chemistry, of electricity, magnetism, crystallisation, the former principles are absolutely of no use, indeed the former laws are no longer valid, the former forces are overcome by others, and the phenomena take place in direct contradiction to them, according to new laws, which, just like the former ones, are original and inexplicable, *i.e.*, cannot be reduced to more general ones. Thus, for example, no one will ever succeed in explaining even the dissolving of a salt in water in accordance with the laws proper to mechanics, much less the more complicated phenomena of chemistry. All this has already been explained at length in the second book of the present work. An exposition of this kind would, as it seems to me, have been of great use in the "Critique of the Teleological Judgment," and would have thrown much light upon what is said there. Such an exposition would have been especially favourable to his excellent remark that a more profound knowledge of the real being, of which the things of nature are the manifestation, would recognise both in the mechanical (according to law) and the apparently intentional effects of nature one and the same ultimate principle, which might serve as the more general ground of explanation of them both. Such a principle I hope I have given by establishing the will as the real thing in itself; and in accordance with it generally in the second book and the supplements to it, but especially in my work "On the Will in Nature," the insight into the inner nature of the apparent design and of the harmony and

agreement of the whole of nature has perhaps become clearer and deeper. Therefore I have nothing more to say about it here.

The reader whom this criticism of the Kantian philosophy interests should not neglect to read the supplement to it which is given in the second essay of the first volume of my "Parerga and Paralipomena," under the title "*Noch einige Erläuterungen zur Kantischen Philosophie*" (Some Further Explanations of the Kantian Philosophy). For it must be borne in mind that my writings, few as they are, were not composed all at once, but successively, in the course of a long life, and with long intervals between them. Accordingly, it must not be expected that all I have said upon one subject should stand together in one place.

Supplements to the First Book.

“ ’Warum willst du dich von uns Allen
Und unsrer Meinung entfernen?’
Ich schreibe nicht euch zu gefallen,
Ihr sollt was lernen.”
— Goethe.

First Half. The Doctrine Of The Idea Of Perception. (To § 1-7 of the First Volume.)

Chapter I. The Standpoint of Idealism.

In boundless space countless shining spheres, about each of which, and illuminated by its light, there revolve a dozen or so of smaller ones, hot at the core and covered with a hard, cold crust, upon whose surface there have been generated from a mouldy film beings which live and know — this is what presents itself to us in experience as the truth, the real, the world. Yet for a thinking being it is a precarious position to stand upon one of those numberless spheres moving freely in boundless space without knowing whence or whither, and to be only one of innumerable similar beings who throng and press and toil, ceaselessly and quickly arising and passing away in time, which has no beginning and no end; moreover, nothing permanent but matter alone and the recurrence of the same varied organised forms, by means of certain ways and channels which are there once for all. All that empirical science can teach is only the more exact nature and law of these events. But now at last modern philosophy especially through Berkeley and Kant, has called to mind that all this is first of all merely a *phenomenon of the brain*, and is affected with such great, so many, and such different *subjective* conditions that its supposed absolute reality vanishes away, and leaves room for an entirely different scheme of the world, which consists of what lies at the foundation of that phenomenon, *i.e.*, what is related to it as the thing in itself is related to its mere manifestation.

"The world is my idea" is, like the axioms of Euclid, a proposition which every one must recognise as true as soon as he understands it; although it is not a proposition which every one understands as soon as he hears it. To have brought this proposition to clear consciousness, and in it the problem of the relation of the ideal and the real, *i.e.*, of the world in the head to the world outside the head, together with the problem of moral freedom, is the distinctive feature of modern philosophy. For it was only after men had spent their labour for thousands of years upon a mere philosophy of the object that they discovered that among the many things that make the world so obscure and doubtful the first and chiefest is this, that however immeasurable and massive it may be, its existence yet hangs by a single thread; and this is the actual consciousness in which it exists. This condition, to which the existence of the world is irrevocably subject, marks it, in spite of all *empirical* reality, with the stamp of *ideality*, and therefore of mere *phenomenal appearance*. Thus on one side at least the world must

be recognised as akin to dreams, and indeed to be classified along with them. For the same function of the brain which, during sleep, conjures up before us a completely objective, perceptible, and even palpable world must have just as large a share in the presentation of the objective world of waking life. Both worlds, although different as regards their matter, are yet clearly moulded in the one form. This form is the intellect, the function of the brain. Descartes was probably the first who attained to the degree of reflection which this fundamental truth demands, and consequently he made it the starting-point of his philosophy, though provisionally only in the form of a sceptical doubt. When he took his *cogito ergo sum* as alone certain, and provisionally regarded the existence of the world as problematical, he really discovered the essential and only right starting-point of all philosophy, and at the same time its *true* foundation. This foundation is essentially and inevitably the *subjective*, the *individual consciousness*. For this alone is and remains immediate; everything else, whatever it may be, is mediated and conditioned through it, and is therefore dependent upon it. Therefore modern philosophy is rightly regarded as starting with Descartes, who was the father of it. Not long afterwards Berkeley followed the same path further, and attained to *idealism* proper, *i.e.*, to the knowledge that the world which is extended in space, thus the objective, material world in general, exists as such simply and solely in our *idea*, and that it is false, and indeed absurd, to attribute to it, *as such*, an existence apart from all idea and independent of the knowing subject, thus to assume matter as something absolute and possessed of real being in itself. But his correct and profound insight into this truth really constitutes Berkeley's whole philosophy; in it he had exhausted himself.

Thus true philosophy must always be idealistic; indeed, it must be so in order to be merely honest. For nothing is more certain than that no man ever came out of himself in order to identify himself directly with things which are different from him; but everything of which he has certain, and therefore immediate, knowledge lies within his own consciousness. Beyond this consciousness, therefore, there can be no *immediate* certainty; but the first principles of a science must have such certainty. For the empirical standpoint of the other sciences it is quite right to assume the objective world as something absolutely given; but not so for the standpoint of philosophy, which has to go back to what is first and original. Only consciousness is immediately given; therefore the basis of philosophy is

limited to facts of consciousness, *i.e.*, it is essentially *idealistic*. Realism which commends itself to the crude understanding, by the appearance which it assumes of being matter-of-fact, really starts from an arbitrary assumption, and is therefore an empty castle in the air, for it ignores or denies the first of all facts, that all that we know lies within consciousness. For that the *objective existence* of things is conditioned through a subject whose ideas they are, and consequently that the objective world exists only as *idea*, is no hypothesis, and still less a dogma, or even a paradox set up for the sake of discussion; but it is the most certain and the simplest truth; and the knowledge of it is only made difficult by the fact that it is indeed so simple, and that it is not every one who has sufficient power of reflection to go back to the first elements of his consciousness of things. There can never be an absolute and independent objective existence; indeed such an existence is quite unintelligible. For the objective, as such, always and essentially has its existence in the consciousness of a subject, is thus the idea of this subject, and consequently is conditioned by it, and also by its forms, the forms of the idea, which depend upon the subject and not on the object.

That *the objective world would exist* even if there existed no conscious being certainly seems at the first blush to be unquestionable, because it can be thought in the abstract, without bringing to light the contradiction which it carries within it. But if we desire to *realise* this abstract thought, that is, to reduce it to ideas of perception, from which alone (like everything abstract) it can have content and truth, and if accordingly we try *to imagine an objective world without a knowing subject*, we become aware that what we then imagine is in truth the opposite of what we intended, is in fact nothing else than the process in the intellect of a knowing subject who perceives an objective world, is thus exactly what we desired to exclude. For this perceptible and real world is clearly a phenomenon of the brain; therefore there lies a contradiction in the assumption that as such it ought also to exist independently of all brains.

The principal objection to the inevitable and essential *ideality of all objects*, the objection which, distinctly or indistinctly, arises in every one, is certainly this: My own person also is an object for some one else, is thus his idea, and yet I know certainly that I would continue to exist even if he no longer perceived me. But all other objects also stand in the same relation to his intellect as I do; consequently they also would continue to exist without

being perceived by him. The answer to this is: That other being as whose object I now regard my person is not absolutely *the subject*, but primarily is a knowing individual. Therefore, if he no longer existed, nay, even if there existed no other conscious being except myself, yet the subject, in whose idea alone all objects exist, would by no means be on that account abolished. For I myself indeed am this subject, as every conscious being is. Consequently, in the case assumed, my person would certainly continue to exist, but still as idea, in my own knowledge. For even by me myself it is always known only indirectly, never immediately; because all existence as idea is indirect. As *object*, *i.e.*, as extended, occupying space and acting, I know my body only in the perception of my brain. This takes place by means of the senses, upon data supplied by which the percipient understanding performs its function of passing from effect to cause, and thereby, in that the eye sees the body or the hands touch it, it constructs that extended figure which presents itself in space as my body. By no means, however, is there directly given me, either in some general feeling of bodily existence or in inner self-consciousness, any extension, form, or activity, which would then coincide with my nature itself, which accordingly, in order so to exist, would require no other being in whose knowledge it might exhibit itself. On the contrary, that general feeling of bodily existence, and also self-consciousness, exists directly only in relation to the *will*, that is, as agreeable or disagreeable, and as active in the acts of will, which for external perception exhibit themselves as actions of the body. From this it follows that the existence of my person or body as *something extended and acting* always presupposes a *knowing being* distinct from it; because it is essentially an existence in apprehension, in the idea, thus an existence *for another*. In fact, it is a phenomenon of brain, just as much whether the brain in which it exhibits itself is my own or belongs to another person. In the first case one's own person divides itself into the knowing and the known, into object and subject, which here as everywhere stand opposed to each other, inseparable and irreconcilable. If, then, my own person, in order to exist as such, always requires a knowing subject, this will at least as much hold good of the other objects for which it was the aim of the above objection to vindicate an existence independent of knowledge and its subject.

However, it is evident that the existence which is conditioned through a knowing subject is only the existence in space, and therefore that of an

extended and active being. This alone is always something known, and consequently *an existence for another*. On the other hand, every being that exists in this way may yet have *an existence for itself*, for which it requires no subject. Yet this existence for itself cannot be extension and activity (together space-occupation), but is necessarily a being of another kind, that of a thing in itself, which, as such, can never be an *object*. This, then, would be the answer to the leading objection set forth above, which accordingly does not overthrow the fundamental truth that the objectively given world can only exist in the idea, thus only for a subject.

We have further to remark here that Kant also, so long at least as he remained consistent, can have thought no *objects* among his things in themselves. For this follows from the fact that he proves that space, and also time, are mere forms of our perception, which consequently do not belong to things in themselves. What is neither in space nor in time can be no *object*; thus the being of *things in themselves* cannot be objective, but of quite a different kind, a metaphysical being. Consequently that Kantian principle already involves this principle also, that the *objective* world exists only as *idea*.

In spite of all that one may say, nothing is so persistently and ever anew misunderstood as *Idealism*, because it is interpreted as meaning that one denies the *empirical* reality of the external world. Upon this rests the perpetual return to the appeal to common sense, which appears in many forms and guises; for example, as an "irresistible conviction" in the Scotch school, or as Jacobi's *faith* in the reality of the external world. The external world by no means presents itself, as Jacobi declares, upon credit, and is accepted by us upon trust and faith. It presents itself as that which it is, and performs directly what it promises. It must be remembered that Jacobi, who set up such a credit or faith theory of the world, and had the fortune to impose it upon a few professors of philosophy, who for thirty years have philosophised upon the same lines lengthily and at their ease, is the same man who once denounced Lessing as a Spinozist, and afterwards denounced Schelling as an atheist, and who received from the latter the well-known and well-deserved castigation. In keeping with such zeal, when he reduced the external world to a mere matter of faith he only wished to open the door to faith in general, and to prepare belief for that which was afterwards really to be made a matter of belief; as if, in order to introduce a paper currency, one should seek to appeal to the fact that the value of the ringing coin also

depends merely on the stamp which the State has set upon it. Jacobi, in his doctrine that the reality of the external world is assumed upon faith, is just exactly "the transcendental realist who plays the empirical idealist" censured by Kant in the "Critique of Pure Reason," first edition, p. 369.

The true idealism, on the contrary, is not the empirical but the transcendental. This leaves the empirical reality of the world untouched, but holds fast to the fact that every *object*, thus the empirically real in general, is conditioned in a twofold manner by the subject; in the first place *materially* or as *object* generally, because an objective existence is only conceivable as opposed to a subject, and as its idea; in the second place *formally*, because the mode of existence of an object, *i.e.*, its being perceived (space, time, causality), proceeds from the subject, is pre-arranged in the subject. Therefore with the simple or Berkeleian idealism, which concerns the object in general, there stands in immediate connection the Kantian idealism, which concerns the specially given *mode or manner* of objective existence. This proves that the whole material world, with its bodies, which are extended in space and, by means of time, have causal relations to each other, and everything that depends upon this — that all this is not something which is there *independently* of our head, but essentially presupposes the functions of our brain *by means of which* and *in* which alone *such* an objective arrangement of things is possible. For time, space, and causality, upon which all those real and objective events rest, are themselves nothing more than functions of the brain; so that thus the unchangeable *order* of things which affords the criterion and clue to their empirical reality itself proceeds only from the brain, and has its credentials from this alone. All this Kant has expounded fully and thoroughly; only he does not speak of the brain, but calls it "the faculty of knowledge." Indeed he has attempted to prove that when that objective order in time, space, causality, matter, &c., upon which all the events of the real world ultimately rest, is properly considered, it cannot even be conceived as a self-existing order, *i.e.*, an order of the thing in itself, or as something absolutely objective and unconditionally given, for if one tries to think this out it leads to contradictions. To accomplish this was the object of the antinomies, but in the appendix to my work I have proved the failure of the attempt. On the other hand, the Kantian doctrine, even without the antinomies, leads to the insight that things and the whole mode of their existence are inseparably bound up with our consciousness of them. Therefore whoever has distinctly

grasped this soon attains to the conviction that the assumption that things also exist as such, apart from and independently of our consciousness, is really absurd. That we are so deeply involved in time, space, causality, and the whole regular process of experience which rests upon them, that we (and indeed the brutes) are so perfectly at home, and know how to find our way from the first — this would not be possible if our intellect were one thing and things another, but can only be explained from the fact that both constitute one whole, the intellect itself creates that order, and exists only for things, while they, on the other hand, exist only for it.

But even apart from the deep insight, which only the Kantian philosophy gives, the inadmissibility of the assumption of absolute realism which is so obstinately clung to may be directly shown, or at least made capable of being felt, by the simple exhibition of its meaning in the light of such considerations as the following. According to realism, the world is supposed to exist, as we know it, independently of this knowledge. Let us once, then, remove all percipient beings from it, and leave only unorganised and vegetable nature. Rock, tree, and brook are there, and the blue heaven; sun, moon, and stars light this world, as before; yet certainly in vain, for there is no eye to see it. Let us now in addition place in it a percipient being. Now that world presents itself *again* in his brain, and repeats itself within it precisely as it was formerly without it. Thus to the *first* world a *second* has been added, which, although completely separated from it, resembles it to a nicety. And now the *subjective* world of this perception is precisely so constituted in *subjective*, known space as the *objective* world in *objective*, infinite space. But the subjective world has this advantage over the objective, the knowledge that that space, outside there, is infinite; indeed it can also give beforehand most minutely and accurately the whole constitution or necessary properties of all relations which are possible, though not yet actual, in that space, and does not require to examine them. It can tell just as much with regard to the course of time, and also with regard to the relation of cause and effect which governs the changes in that external world. I think all this, when closely considered, turns out absurd enough, and hence leads to the conviction that that absolute objective world outside the head, independent of it and prior to all knowledge, which at first we imagined ourselves to conceive, is really no other than the second, the world which is known *subjectively*, the world of idea, as which alone we are actually able to conceive it. Thus of its own accord the assumption forces

itself upon us, that the world, as we know it, exists also only for our knowledge, therefore in the *idea* alone, and not a second time outside of it.[12] In accordance, then, with this assumption, the thing in itself, *i.e.*, that which exists independently of our knowledge and of every knowledge, is to be regarded as something completely different from the *idea* and all its attributes, thus from objectivity in general. What this is will be the subject of our second book.

On the other hand, the controversy concerning the reality of the external world considered in § 5 of the first volume rests upon the assumption, which has just been criticised, of an objective and a subjective world both in *space*, and upon the impossibility which arises in connection with this presupposition of a transition from one to the other, a bridge between the two. Upon this controversy I have still to add the following remarks.

The subjective and the objective do not constitute a continuous whole. That of which we are immediately conscious is bounded by the skin, or rather by the extreme ends of the nerves which proceed from the cerebral system. Beyond this lies a world of which we have no knowledge except through pictures in our head. Now the question is, whether and how far there is a world independent of us which corresponds to these pictures. The relation between the two could only be brought about by means of the law of causality; for this law alone leads from what is given to something quite different from it. But this law itself has first of all to prove its validity. Now it must either be of *objective* or of *subjective* origin; but in either case it lies upon one or the other side, and therefore cannot supply the bridge between them. If, as Locke and Hume assume, it is *a posteriori*, thus drawn from experience, it is of *objective* origin, and belongs then itself to the external world which is in question. Therefore it cannot attest the reality of this world, for then, according to Locke's method, causality would be proved from experience, and the reality of experience from causality. If, on the contrary, it is given *a priori*, as Kant has more correctly taught us, then it is of *subjective* origin, and in that case it is clear that with it we remain always in the *subjective* sphere. For all that is actually given *empirically* in perception is the occurrence of a sensation in the organ of sense; and the assumption that this, even in general, must have a cause rests upon a law which is rooted in the form of our knowledge, *i.e.*, in the functions of our brain. The origin of this law is therefore just as subjective as that of the sensation itself. The cause of the given sensation, which is assumed in

consequence of this law, presents itself at once in perception as an *object*, which has space and time for the form of its manifestation. But *these forms* themselves again are entirely of subjective origin; for they are the mode or method of our faculty of perception. That transition from the sensation to its cause which, as I have repeatedly pointed out, lies at the foundation of all sense-perception is certainly sufficient to give us the empirical presence in space and time of an empirical object, and is therefore quite enough for the practical purposes of life; but it is by no means sufficient to afford us any conclusion as to the existence and real nature, or rather as to the intelligible substratum, of the phenomena which in this way arise for us. Thus that on the occasion of certain sensations occurring in my organs of sense there arises in my head a perception of things which are extended in space, permanent in time, and causally efficient by no means justifies the assumption that they also exist in themselves, *i.e.*, that such things with these properties belonging absolutely to themselves exist independently and outside of my head. This is the true outcome of the Kantian philosophy. It coincides with an earlier result of Locke's, which is just as true, but far more easily understood. For although, as Locke's doctrine permits, external things are absolutely assumed as the causes of sensations, yet there can be no *resemblance* between the sensation in which the *effect* consists and the objective nature of the *cause* which occasions it. For the sensation, as organic function, is primarily determined by the highly artificial and complicated nature of our organs of sense. It is therefore merely excited by the external cause, but is then perfected entirely in accordance with its own laws, and thus is completely subjective. Locke's philosophy was the criticism of the functions of sense; Kant has given us the criticism of the functions of the brain. But to all this we have yet to add the Berkeleian result, which has been revised by me, that every object, whatever its origin may be, is *as object* already conditioned by the subject, is in fact merely its *idea*. The aim of realism is indeed the object without subject; but it is impossible even to conceive such an object distinctly.

From this whole inquiry it follows with certainty and distinctness that it is absolutely impossible to attain to the comprehension of the inner nature of things upon the path of mere *knowledge* and *perception*. For knowledge always comes to things from without, and therefore must for ever remain outside them. This end would only be reached if we could find *ourselves* in the inside of things, so that their inner nature would be known to us directly.

Now, how far this is actually the case is considered in my second book. But so long as we are concerned, as in this first book, with objective comprehension, that is, with *knowledge*, the world is, and remains for us, a mere *idea*, for here there is no possible path by which we can cross over to it.

But, besides this, a firm grasp of the point of view of *idealism* is a necessary counterpoise to that of *materialism*. The controversy concerning the *real* and the *ideal* may also be regarded as a controversy concerning the existence of *matter*. For it is the reality or ideality of this that is ultimately in question. Does matter, as such, exist only in our *idea*, or does it also exist independently of it? In the latter case it would be the thing in itself; and whoever assumes a self-existent matter must also, consistently, be a materialist, *i.e.*, he must make matter the principle of explanation of all things. Whoever, on the contrary, denies its existence as a thing in itself is *eo ipso* an idealist. Among the moderns only Locke has definitely and without ambiguity asserted the reality of matter; and therefore his teaching led, in the hands of Condillac, to the sensualism and materialism of the French. Only Berkeley directly and without modifications denies matter. The complete antithesis is thus that of idealism and materialism, represented in its extremes by Berkeley and the French materialists (Hollbach). Fichte is not to be mentioned here: he deserves no place among true philosophers; among those elect of mankind who, with deep earnestness, seek not their own things but the *truth*, and therefore must not be confused with those who, under this pretence, have only their personal advancement in view. Fichte is the father of the *sham philosophy*, of the *disingenuous* method which, through ambiguity in the use of words, incomprehensible language, and sophistry, seeks to deceive, and tries, moreover, to make a deep impression by assuming an air of importance — in a word, the philosophy which seeks to bamboozle and humbug those who desire to learn. After this method had been applied by Schelling, it reached its height, as every one knows, in Hegel, in whose hands it developed into pure charlatanism. But whoever even names this Fichte seriously along with Kant shows that he has not even a dim notion of what Kant is. On the other hand, materialism also has its warrant. It is just as true that the knower is a product of matter as that matter is merely the idea of the knower; but it is also just as one-sided. For materialism is the philosophy of the subject that forgets to take account of itself. And, accordingly, as against the assertion

that I am a mere modification of matter, this must be insisted upon, that all matter exists merely in my idea; and it is no less right. A knowledge, as yet obscure, of these relations seems to have been the origin of the saying of Plato, "ὑλη αληθινον ψευδος" (*materia mendacium verax*).

Realism necessarily leads, as we have said, to *materialism*. For if empirical perception gives us things in themselves, as they exist independently of our knowledge, experience also gives us the *order* of things in themselves, *i.e.*, the true and sole order of the world. But this path leads to the assumption that there is only *one* thing in itself, matter; of which all other things are modifications; for the course of nature is here the absolute and only order of the world. To escape from these consequences, while realism remained in undisputed acceptance, spiritualism was set up, that is, the assumption of a second substance outside of and along with matter, an *immaterial substance*. This dualism and spiritualism, equally unsupported by experience and destitute of proof and comprehensibility, was denied by Spinoza, and was proved to be false by Kant, who dared to do so because at the same time he established idealism in its rights. For with realism materialism, as the counterpoise of which spiritualism had been devised, falls to the ground of its own accord, because then matter and the course of nature become mere phenomena, which are conditioned by the intellect, as they have their existence only in its *idea*. Accordingly spiritualism is the delusive and false safeguard against materialism, while the real and true safeguard is idealism, which, by making the objective world dependent upon us, gives the needed counterpoise to the position of dependence upon the objective world, in which we are placed by the course of nature. The world from which I part at death is, in another aspect, only my idea. The centre of gravity of existence falls back into the *subject*. What is proved is not, as in spiritualism, that the knower is independent of matter, but that all matter is dependent on him. Certainly this is not so easy to comprehend or so convenient to handle as spiritualism, with its two substances; but χαλεπα τα καλα.

In opposition to the *subjective* starting-point, "the world is my idea," there certainly stands provisionally with equal justification the *objective* starting-point, "the world is matter," or "matter alone is absolute" (since it alone is not subject to becoming and passing away), or "all that exists is matter." This is the starting-point of Democritus, Leucippus, and Epicurus. But, more closely considered, the departure from the subject retains a real

advantage; it has the start by one perfectly justified step. For consciousness alone is the *immediate*: but we pass over this if we go at once to matter and make it our starting-point. On the other hand, it would certainly be possible to construct the world from matter and its properties if these were correctly, completely, and exhaustively known to us (which is far from being the case as yet). For all that has come to be has become actual through *causes*, which could operate and come together only by virtue of the *fundamental forces of matter*. But these must be perfectly capable of demonstration at least objectively, even if subjectively we never attain to a knowledge of them. But such an explanation and construction of the world would not only have at its foundation the assumption of an existence in itself of matter (while in truth it is conditioned by the subject), but it would also be obliged to allow all the *original qualities* in this matter to pass current and remain absolutely inexplicable, thus as *qualitates occultæ*. (Cf. § 26, 27 of the first volume.) For matter is only the vehicle of these forces, just as the law of causality is only the arranger of their manifestations. Therefore such an explanation of the world would always remain merely relative and conditioned, properly the work of a *physical science*, which at every step longed for a *metaphysic*. On the other hand, there is also something inadequate about the subjective starting-point and first principle, "the world is my idea," partly because it is one-sided, since the world is far more than that (the thing in itself, will), and indeed its existence as idea is to a certain extent only accidental to it; but partly also because it merely expresses the fact that the object is conditioned by the subject, without at the same time saying that the subject, as such, is also conditioned by the object. For the assertion, "the subject would still remain a knowing being if it had no object, *i.e.*, if it had absolutely no idea," is just as false as the assertion of the crude understanding, "the world, the object, would still exist, even if there were no subject." A consciousness without an object is no consciousness. A thinking subject has conceptions for its object; a subject of sense perception has objects with the qualities corresponding to its organisation. If we rob the subject of all special characteristics and forms of its knowledge, all the properties of the object vanish also, and nothing remains but *matter without form and quality*, which can just as little occur in experience as a subject without the forms of its knowledge, but which remains opposed to the naked subject as such, as its reflex, which can only disappear along with it. Although materialism pretends to postulate nothing more than this matter — for instance, atoms

— yet it unconsciously adds to it not only the subject, but also space, time, and causality, which depend upon special properties of the subject.

The world as idea, the objective world, has thus, as it were, two poles; the simple knowing subject without the forms of its knowledge, and crude matter without form and quality. Both are completely unknowable; the subject because it is that which knows, matter because without form and quality it cannot be perceived. Yet both are fundamental conditions of all empirical perception. Thus the knowing subject, merely as such, which is a presupposition of all experience, stands opposed as its pure counterpart to the crude, formless, and utterly dead (*i.e.*, will-less) matter, which is given in no experience, but which all experience presupposes. This subject is not in time, for time is only the more definite form of all its ideas. The matter which stands over against it is, like it, eternal and imperishable, endures through all time, but is, properly speaking, not extended, for extension gives form, thus it has no spatial properties. Everything else is involved in a constant process of coming into being and passing away, while these two represent the unmoved poles of the world as idea. The permanence of matter may therefore be regarded as the reflex of the timelessness of the pure subject, which is simply assumed as the condition of all objects. Both belong to phenomena, not to the thing in itself, but they are the framework of the phenomenon. Both are arrived at only by abstraction, and are not given immediately, pure and for themselves.

The fundamental error of all systems is the failure to understand this truth. *Intelligence and matter are correlates*, *i.e.*, the one exists only for the other, both stand and fall together, the one is only the reflex of the other. Indeed they are really *one and the same thing* regarded from two opposite points of view; and this one thing, I am here anticipating, is the manifestation of the will, or the thing in itself. Consequently both are secondary, and therefore the origin of the world is not to be sought in either of the two. But because of their failure to understand this, all systems (with the exception perhaps of that of Spinoza) sought the origin of all things in one of these two. Some of them, on the one hand, suppose an intelligence, νους, as the absolutely First and δημιουργος, and accordingly in this allow an idea of things and of the world to precede their actual existence; consequently they distinguish the real world from the world of idea; which is false. Therefore matter now appears as that through which the two are distinguished, as the thing in itself. Hence arises the difficulty of procuring

this matter, the ὐλη, so that when added to the mere idea of the world it may impart reality to it. That original intelligence must now either find it ready to hand, in which case it is just as much an absolute First as that intelligence itself, and we have then two absolute Firsts, the δημιουργος and the ὐλη; or the absolute intelligence must create this matter out of nothing, an assumption which our understanding refuses to make, for it is only capable of comprehending changes in matter, and not that matter itself should come into being or pass away. This rests ultimately upon the fact that matter is essential, the correlate of the understanding. On the other hand, the systems opposed to these, which make the other of the two correlates, that is, matter, the absolute First, suppose a matter which would exist without being perceived; and it has been made sufficiently clear by all that has been said above that this is a direct contradiction, for by the existence of matter we always mean simply its being perceived. But here they encounter the difficulty of bringing to this matter, which alone is their absolute First, the intelligence which is finally to experience it. I have shown this weak side of materialism in § 7 of the first volume. For me, on the contrary, matter and intelligence are inseparable correlates, which exist only for each other, and therefore merely relatively. Matter is the idea of the intelligence; the intelligence is that in whose idea alone matter exists. The two together constitute *the world as idea*, which is just Kant's *phenomenon*, and consequently something secondary. What is primary is that which manifests itself, *the thing in itself*, which we shall afterwards discover is the will. This is in itself neither the perceiver nor the perceived, but is entirely different from the mode of its manifestation.

As a forcible conclusion of this important and difficult discussion I shall now personify these two abstractions, and present them in a dialogue after the fashion of Prabodha Tschandro Daya. It may also be compared with a similar dialogue between matter and form in the "*Duodecim Principia Philosophiæ*" of Raymund Lully, c. 1 and 2.

The Subject.

I am, and besides me there is nothing. For the world is my idea.

Matter.

Presumptuous delusion! I, I am, and besides me there is nothing, for the world is my fleeting form. Thou art a mere result of a part of this form and altogether accidental.

The Subject.

What insane arrogance! Neither thou nor thy form would exist without me; ye are conditioned by me. Whosoever thinks me away, and believes he can still think ye there, is involved in gross delusion, for your existence apart from my idea is a direct contradiction, a meaningless form of words. *Ye are* simply means ye are perceived by me. My idea is the sphere of your existence; therefore I am its first condition.

Matter.

Fortunately the audacity of your assertion will soon be put to silence in reality and not by mere words. Yet a few moments and thou actually art no more. With all thy boasting thou hast sunk into nothing, vanished like a shadow, and shared the fate of all my transitory forms. But I, I remain, unscathed and undiminished, from age to age, through infinite time, and behold unshaken the play of my changing form.

The Subject.

This infinite time through which thou boastest that thou livest, like the infinite space which thou fillest, exists only in my idea. Indeed it is merely the form of my idea which I bear complete in myself, and in which thou exhibitest thyself, which receives thee, and through which thou first of all existest. But the annihilation with which thou threatenest me touches me not; were it so, then wouldst thou also be annihilated. It merely affects the individual, which for a short time is my vehicle, and which, like everything else, is my idea.

Matter.

And if I concede this, and go so far as to regard thy existence, which is yet inseparably linked to that of these fleeting individuals, as something absolute, it yet remains dependent upon mine. For thou art subject only so far as thou hast an object; and this object I am. I am its kernel and content, that which is permanent in it, that which holds it together, and without which it would be as disconnected, as wavering, and unsubstantial as the dreams and fancies of thy individuals, which have yet borrowed from me even the illusive content they possess.

The Subject.

Thou dost well to refrain from contesting my existence on the ground that it is linked to individuals; for, as inseparably as I am joined to them, thou art joined to thy sister, Form, and hast never appeared without her. No eye hath yet seen either thee or me naked and isolated; for we are both mere abstractions. It is in reality *one* being that perceives itself and is perceived

by itself, but whose real being cannot consist either in perceiving or in being perceived, since these are divided between us two.

Both.

We are, then, inseparably joined together as necessary parts of one whole, which includes us both and exists through us. Only a misunderstanding can oppose us two hostilely to each other, and hence draw the false conclusion that the one contests the existence of the other, with which its own existence stands or falls.

This whole, which comprehends both, is the world as idea, or the world of phenomena. When this is taken away there remains only what is purely metaphysical, the thing in itself, which in the second book we shall recognise as the will.

Chapter II. The Doctrine of Perception or Knowledge Of The Understanding.

With all *transcendental* ideality the objective world retains *empirical* reality; the object is indeed not the thing in itself, but as an empirical object it is real. It is true that space is only in my head; but empirically my head is in space. The law of causality can certainly never enable us to get quit of idealism by building a bridge between things in themselves and our knowledge of them, and thus certifying the absolute reality of the world, which exhibits itself in consequence of its application; but this by no means does away with the causal relation of objects to each other, thus it does not abolish the causal relation which unquestionably exists between the body of each knowing person and all other material objects. But the law of causality binds together only phenomena, and does not lead beyond them. With that law we are and remain in the world of objects, *i.e.*, the world of phenomena, or more properly the world of ideas. Yet the whole of such a world of experience is primarily conditioned by the knowledge of a subject in general as its necessary presupposition, and then by the special forms of our perception and apprehension, thus necessarily belongs to the merely *phenomenal*, and has no claim to pass for the world of things in themselves. Indeed the subject itself (so far as it is merely the *knowing* subject) belongs to the merely phenomenal, of which it constitutes the complementary half.

Without application of the law of causality, however, perception of an *objective* world could never be arrived at; for this perception is, as I have often explained, essentially matter of the *intellect*, and not merely of the *senses*. The senses afford us mere *sensation*, which is far from being *perception*. The part played by sensations of the senses in perception was distinguished by Locke under the name *secondary qualities*, which he rightly refused to ascribe to things in themselves. But Kant, carrying Locke's method further, distinguished also, and refused to ascribe to things in themselves what belongs to the working up of this material (the sensations) by the brain. The result was, that in this was included all that Locke had left to things in themselves as *primary* qualities — extension, form, solidity, &c. — so that with Kant the thing in itself was reduced to a completely unknown quantity = *x*. With Locke accordingly the thing in itself is certainly without colour, sound, smell, taste, neither warm nor cold,

neither soft nor hard, neither smooth nor rough; yet it has still extension and form, it is impenetrable, at rest or in motion, and has mass and number. With Kant, on the other hand, it has laid aside all these latter qualities also, because they are only possible by means of time, space, and causality, and these spring from an intellect (brain), just as colours, tones, smells, &c., originate in the nerves of the organs of sense. The thing in itself has with Kant become spaceless, unextended, and incorporeal. Thus what the mere senses bring to the perception, in which the objective world exists, stands to what is supplied by the *functions of the brain* (space, time, causality) as the mass of the nerves of sense stand to the mass of the brain, after subtracting that part of the latter which is further applied to thinking proper, *i.e.*, to abstract ideas, and is therefore not possessed by the brutes. For as the nerves of the organs of sense impart to the phenomenal objects colour, sound, taste, smell, temperature, &c., so the brain imparts to them extension, form, impenetrability, the power of movement, &c., in short all that can only be presented in perception by means of time, space, and causality. How small is the share of the senses in perception, compared with that of the intellect, is also shown by a comparison of the nerve apparatus for receiving impressions with that for working them up. The mass of the nerves of sensation of the whole of the organs of sense is very small compared with that of the brain, even in the case of the brutes, whose brain, since they do not, properly speaking, *i.e.*, in the abstract, think, is merely used for effecting perception, and yet when this is complete, thus in the case of mammals, has a very considerable mass, even after the cerebellum, whose function is the systematic guidance of movements, has been taken away.

That excellent book by Thomas Reid, the “Inquiry into the Human Mind” (first edition, 1764; 6th edition, 1810), as a *negative* proof of the Kantian truths, affords us a very thorough conviction of the inadequacy of the senses to produce the objective perception of things, and also of the non-empirical origin of the perception of space and time. Reid refutes Locke’s doctrine that perception is a product of the senses, by a thorough and acute demonstration that the collective sensations of the senses do not bear the least resemblance to the world as known in perception, and especially that the five primary qualities of Locke (extension, form, solidity, movement, and number) absolutely could not be afforded us by any sensation of the senses. Accordingly he gives up the question as to the mode

of origination and the source of perception as completely insoluble; and although altogether unacquainted with Kant, he gives us, as it were, according to the *regula falsi*, a thorough proof of the intellectual nature of perception (really first explained by me as a consequence of the Kantian doctrine), and also of the *a priori* source, discovered by Kant, of its constituent elements, space, time, and causality, from which those primary qualities of Locke first proceed, but by means of which they are easily constructed. Thomas Reid's book is very instructive and well worth reading — ten times more so than all the philosophy together that has been written since Kant. Another indirect proof of the same doctrine, though in the way of error, is afforded by the French sensational philosophers, who, since Condillac trod in the footsteps of Locke, have laboured to show once for all that the whole of our perception and thinking can be referred to mere sensations (*penser c'est sentir*), which, after Locke's example, they call *idées simples*, and through the mere coming together and comparison of which the whole objective world is supposed to build itself up in our heads. These gentlemen certainly have *des idées bien simples*. It is amusing to see how, lacking alike the profundity of the German and the honesty of the English philosopher, they turn the poor material of sensation this way and that way, and try to increase its importance, in order to construct out of it the deeply significant phenomena of the world of perception and thought. But the man constructed by them would necessarily be an *Anencephalus*, a *Tête de crapaud*, with only organs of sense and without a brain. To take only a couple of the better attempts of this sort out of a multitude of others, I may mention as examples Condorcet at the beginning of his book, "*Des Progrès de l'Esprit Humain*," and Tourtual on Sight, in the second volume of the *"Scriptures Ophthalmologici Minores," edidit Justus Radius* (1828).

The feeling of the insufficiency of a purely sensationalistic explanation of perception is in like manner shown in the assertion which was made shortly before the appearance of the Kantian philosophy, that we not only have *ideas* of things called forth by sensation, but apprehend the *things themselves* directly, although they lie outside us — which is certainly inconceivable. And this was not meant in some idealistic sense, but was said from the point of view of common realism. This assertion is well and pointedly put by the celebrated Euler in his "Letters to a German Princess," vol. ii. p. 68. He says: "I therefore believe that the sensations (of the senses) contain something more than philosophers imagine. They are not merely

empty perceptions of certain impressions made in the brain. They do not give the soul mere *ideas* of things, *but actually place before it objects* which exist outside it, although we cannot conceive how this really happens." This opinion is explained by the following facts. Although, as I have fully proved, perception is brought about by application of the law of causality, of which we are conscious *a priori*, yet in sight the act of the understanding, by means of which we pass from the effect to the cause, by no means appears distinctly in consciousness; and therefore the sensation does not separate itself clearly from the idea which is constructed out of it, as the raw material, by the understanding. Still less can a distinction between object and idea, which in general does not exist, appear in consciousness; but we feel the *things themselves* quite directly, and indeed as lying *outside us*, although it is certain that what is immediate can only be the sensation, and this is confined to the sphere of the body enclosed by our skin. This can be explained from the fact that *outside us* is exclusively a *spatial* determination. But space itself is a form of our faculty of perception, *i.e.*, a function of our brain. Therefore that externality to us to which we refer objects, on the occasion of sensations of sight, is itself really within our heads; for that is its whole sphere of activity. Much as in the theatre we see the mountains, the woods, and the sea, but yet everything is inside the house. From this it becomes intelligible that we perceive things in the relation of externality, and yet in every respect immediately, but have not within us an idea of the things which lie outside us, different from these things. For things are in space, and consequently also external to us only in so far as we *perceive* them. Therefore those things which to this extent we perceive directly, and not mere images of them, are themselves only *our ideas*, and as such exist only in our heads. Therefore we do not, as Euler says, directly perceive the things themselves which are external to us, but rather the things which are perceived by us as external to us are only our ideas, and consequently are apprehended by us immediately. The whole observation given above in Euler's words, and which is quite correct, affords a fresh proof of Kant's Transcendental Æsthetic, and of my theory of perception which is founded upon it, as also of idealism in general. The directness and unconsciousness referred to above, with which in perception we make *the transition from the sensation to its cause*, may be illustrated by an analogous procedure in the use of abstract ideas or thinking. When we read or hear we receive mere words, but we pass from these so immediately

to the conceptions denoted by them, that it is as if we *received the conceptions directly*; for we are absolutely unconscious of the transition from the words to the conceptions. Therefore it sometimes happens that we do not know in what language it was that we read something yesterday which we now remember. Yet that such a transition always takes place becomes apparent if it is once omitted, that is, if in a fit of abstraction we read without thinking, and then become aware that we certainly have taken in all the words but no conceptions. Only when we pass from abstract conceptions to pictures of the imagination do we become conscious of the transposition we have made.

Further, it is really only in perception in the narrowest sense, that is, in *sight*, that in empirical apprehension the transition from the sensation to its cause takes place quite unconsciously. In every other kind of sense perception, on the contrary, the transition takes place with more or less distinct consciousness; therefore, in the case of apprehension through the four coarser senses, its reality is capable of being established as an immediate fact. Thus in the dark we feel a thing for a long time on all sides until from the different effects upon our hands we are able to construct its definite form as their cause. Further, if something feels smooth we sometimes reflect whether we may not have fat or oil upon our hands; and again, if something feels cold we ask ourselves whether it may not be that we have very warm hands. When we hear a sound we sometimes doubt whether it was really an affection of our sense of hearing from without or merely an inner affection of it; then whether it sounded near and weak or far off and strong, then from what direction it came, and finally whether it was the voice of a man or of a brute, or the sound of an instrument; thus we investigate the cause of each effect we experience. In the case of smell and taste uncertainty as to the objective nature of the cause of the effect felt is of the commonest occurrence, so distinctly are the two separated here. The fact that *in sight* the transition from the effect to the cause occurs quite unconsciously, and hence the illusion arises that this kind of perception is perfectly direct, and consists simply in the sensation alone without any operation of the understanding — this has its explanation partly in the great perfection of the organ of vision, and partly in the exclusively rectilineal action of light. On account of the latter circumstance the impression itself leads directly to the place of the cause, and since the eye is capable of perceiving with the greatest exactness and at a glance all the fine

distinctions of light and shade, colour and outline, and also the data in accordance with which the understanding estimates distance, it thus happens that in the case of impressions of this sense the operation of the understanding takes place with such rapidity and certainty that we are just as little conscious of it as of spelling when we read. Hence arises the delusion that the sensation itself presents us directly with the objects. Yet it is just in sight that the operation of the *understanding*, consisting in the knowledge of the cause from the effect, is most significant. By means of it what is felt doubly, with two eyes, is perceived as single; by means of it the impression which strikes the retina upside down, in consequence of the crossing of the rays in the pupils, is put right by following back the cause of this in the same direction, or as we express ourselves, we see things upright although their image in the eye is reversed; and finally by means of the operation of the understanding magnitude and distance are estimated by us in direct perception from five different data, which are very clearly and beautifully described by Dr. Thomas Reid. I expounded all this, and also the proofs which irrefutably establish the *intellectual nature of perception*, as long ago as 1816, in my essay "On Sight and Colour" (second edition, 1854; third edition, 1870), and with important additions fifteen years later in the revised Latin version of it which is given under the title, "*Theoria Colorum Physiologica Eademque Primaria*," in the third volume of the "*Scriptores Ophthalmologici Minores*," published by Justus Radius in 1830; yet most fully and thoroughly in the second (and third) edition of my essay "On the Principle of Sufficient Reason," § 21. Therefore on this important subject I refer to these works, so as not to extend unduly the present exposition.

On the other hand, an observation which trenches on the province of æsthetics may find its place here. It follows from the proved intellectual nature of perception that the sight of beautiful objects — for example, of a beautiful view — is also a *phenomenon of the brain*. Its purity and completeness, therefore, depends not merely on the object, but also upon the quality of the brain, its form and size, the fineness of its texture, and the stimulation of its activity by the strength of the pulse of the arteries which supply it. Accordingly the same view appears in different heads, even when the eyes are equally acute, as different as, for example, the first and last impressions of a copper plate that has been much used. This is the explanation of the difference of capacity for enjoying natural beauty, and

consequently also for reproducing it, *i.e.*, for occasioning a similar phenomenon of the brain by means of an entirely different kind of cause, the arrangement of colours on a canvas.

The apparent immediacy of perception, depending on its entire intellectuality, by virtue of which, as Euler says, we apprehend the thing itself, and as external to us, finds an analogy in the way in which we feel the parts of our own bodies, especially when they suffer pain, which when we do feel them is generally the case. Just as we imagine that we perceive things where they are, while the perception really takes place in the brain, we believe that we feel the pain of a limb in the limb itself, while in reality it also is felt in the brain, to which it is conducted by the nerve of the affected part. Therefore, only the affections of those parts whose nerves go to the brain are felt, and not those of the parts whose nerves belong to the sympathetic system, unless it be that an unusually strong affection of these parts penetrates by some roundabout way to the brain, where yet for the most part it only makes itself known as a dull sense of discomfort, and always without definite determination of its locality. Hence, also, it is that we do not feel injuries to a limb whose nerve-trunk has been severed or ligatured. And hence, finally, the man who has lost a limb still sometimes feels pain in it, because the nerves which go to the brain are still there. Thus, in the two phenomena here compared, what goes on in the brain is apprehended as outside of it; in the case of perception, by means of the understanding, which extends its feelers into the outer world; in the case of the feeling of our limbs, by means of the nerves.

Chapter III. On The Senses.

It is not the object of my writings to repeat what has been said by others, and therefore I only make here some special remarks of my own on the subject of the senses.

The senses are merely the channels through which the brain receives from without (in the form of sensations) the materials which it works up into ideas of perception. Those sensations which principally serve for the objective comprehension of the external world must in themselves be neither agreeable nor disagreeable. This really means that they must leave the will entirely unaffected. Otherwise the sensation *itself* would attract our attention, and we would remain at the *effect* instead of passing to the *cause*, which is what is aimed at here. For it would bring with it that marked superiority, as regards our consideration, which the will always has over the mere idea, to which we only turn when the will is silent. Therefore colours and sounds are in themselves, and so long as their impression does not pass the normal degree, neither painful nor pleasurable sensations, but appear with the indifference that fits them to be the material of pure objective perception. This is as far the case as was possible in a body which is in itself through and through will; and just in this respect it is worthy of admiration. Physiologically it rests upon the fact that in the organs of the nobler senses, thus in sight and hearing, the nerves which have to receive the specific outward impression are quite insusceptible to any sensation of pain, and know no other sensation than that which is specifically peculiar to them, and which serves the purpose of mere apprehension. Thus the retina, as also the optic nerve, is insensible to every injury; and this is also the case with the nerve of hearing. In both organs pain is only felt in their other parts, the surroundings of the nerve of sense which is peculiar to them, never in this nerve itself. In the case of the eye such pain is felt principally in the *conjunctiva*; in the case of the ear, in the *meatus auditorius*. Even with the brain this is the case, for if it is cut into directly, thus from above, it has no feeling. Thus only on account of this indifference with regard to the will which is peculiar to them are the sensations of the eye capable of supplying the understanding with such multifarious and finely distinguished data, out of which it constructs in our head the marvellous objective world, by the application of the law of causality upon

the foundation of the pure perceptions of space and time. Just that freedom from affecting the will which is characteristic of sensations of colour enables them, when their energy is heightened by transparency, as in the glow of an evening sky, in painted glass, and the like, to raise us very easily into the state of pure objective will-less perception, which, as I have shown in my third book, is one of the chief constituent elements of the æsthetic impression. Just this indifference with regard to the will fits sounds to supply the material for denoting the infinite multiplicity of the conceptions of the reason.

Outer sense, that is, receptivity for external impressions as pure data for the understanding, is divided into *five senses*, and these accommodate themselves to the four elements, *i.e.*, the four states of aggregation, together with that of imponderability. Thus the sense for what is firm (earth) is touch; for what is fluid (water), taste; for what is in the form of vapour, *i.e.*, volatile (vapour, exhalation), smell; for what is permanently elastic (air), hearing; for what is imponderable (fire, light), sight. The second imponderable, heat, is not properly an object of the senses, but of general feeling, and therefore always affects the *will* directly, as agreeable or disagreeable. From this classification there also follows the relative dignity of the senses. Sight has the highest rank, because its sphere is the widest and its susceptibility the finest. This rests upon the fact that what affects it is an imponderable, that is, something which is scarcely corporeal, but is *quasi* spiritual. Hearing has the second place, corresponding to air. However, touch is a more thorough and well-informed sense. For while each of the other senses gives us only an entirely one-sided relation to the object, as its sound, or its relation to light, touch, which is closely bound up with general feeling and muscular power, supplies the understanding with the data at once for the form, magnitude, hardness, softness, texture, firmness, temperature, and weight of bodies, and all this with the least possibility of illusion and deception, to which all the other senses are far more subject. The two lowest senses, smell and taste, are no longer free from a direct affection of the will, that is, they are always agreeably or disagreeably affected, and are therefore more subjective than objective.

Sensations of hearing are exclusively in *time*, and therefore the whole nature of music consists in degrees of time, upon which depends both the quality or pitch of tones, by means of vibrations, and also their quantity or duration, by means of time. The sensations of sight, on the other hand, are

primarily and principally in *space*; but secondarily, by reason of their duration, they are also in time.

Sight is the sense of the understanding which perceives; hearing is the sense of the reason which thinks and apprehends. Words are only imperfectly represented by visible signs; and therefore I doubt whether a deaf and dumb man, who can read, but has no idea of the sound of the words, works as quickly in thinking with the mere visible signs of conceptions as we do with the real, *i.e.*, the audible words. If he cannot read, it is well known that he is almost like an irrational animal, while the man born blind is from the first a thoroughly rational being.

Sight is an *active*, hearing a *passive* sense. Therefore sounds affect our mind in a disturbing and hostile manner, and indeed they do so the more in proportion as the mind is active and developed; they distract all thoughts and instantly destroy the power of thinking. On the other hand, there is no analogous disturbance through the eye, no direct effect of what is seen, *as such*, upon the activity of thought (for naturally we are not speaking here of the influence which the objects looked at have upon the will); but the most varied multitude of things before our eyes admits of entirely unhindered and quiet thought. Therefore the thinking mind lives at peace with the eye, but is always at war with the ear. This opposition of the two senses is also confirmed by the fact that if deaf and dumb persons are cured by galvanism they become deadly pale with terror at the first sounds they hear (Gilbert's "*Annalen der Physik*," vol. x. p. 382), while blind persons, on the contrary, who have been operated upon, behold with ecstasy the first light, and unwillingly allow the bandages to be put over their eyes again. All that has been said, however, can be explained from the fact that hearing takes place by means of a mechanical vibration of the nerve of hearing which is at once transmitted to the brain, while seeing, on the other hand, is a real *action* of the retina which is merely stimulated and called forth by light and its modifications; as I have shown at length in my physiological theory of colours. But this whole opposition stands in direct conflict with that coloured-ether, drum-beating theory which is now everywhere unblushingly served up, and which seeks to degrade the eye's sensation of light to a mechanical vibration, such as primarily that of hearing actually is, while nothing can be more different than the still, gentle effect of light and the alarm-drum of hearing. If we add to this the remarkable circumstance that although we hear with two ears, the sensibility of which is often very

different, yet we never hear a sound double, as we often see things double with our two eyes, we are led to the conjecture that the sensation of hearing does not arise in the labyrinth or in the cochlea, but deep in the brain where the two nerves of hearing meet, and thus the impression becomes simple. But this is where the *pons Varolii* encloses the *medulla oblongata*, thus at the absolutely lethal spot, by the injury of which every animal is instantly killed, and from which the nerve of hearing has only a short course to the labyrinth, the seat of acoustic vibration. Now it is just because its source is here, in this dangerous place, in which also all movement of the limbs originates, that we start at a sudden noise; which does not occur in the least degree when we suddenly see a light; for example, a flash of lightning. The optic nerve, on the contrary, proceeds from its *thalami* much further forward (though perhaps its source lies behind them), and throughout its course is covered by the anterior lobes of the brain, although always separated from them till, having extended quite out of the brain, it is spread out in the retina, upon which, on stimulation by light, the sensation first arises, and where it is really localised. This is shown in my essay upon sight and colour. This origin of the auditory nerve explains, then, the great disturbance which the power of thinking suffers from sound, on account of which thinking men, and in general all people of much intellect, are without exception absolutely incapable of enduring any noise. For it disturbs the constant stream of their thoughts, interrupts and paralyses their thinking, just because the vibration of the auditory nerve extends so deep into the brain, the whole mass of which feels the oscillations set up through this nerve, and vibrates along with them, and because the brains of such persons are more easily moved than those of ordinary men. On the same readiness to be set in motion, and capacity for transmission, which characterises their brains depends the fact that in the case of persons like these every thought calls forth so readily all those analogous or related to it whereby the similarities, analogies, and relations of things in general come so quickly and easily into their minds; that the same occasion which millions of ordinary minds have experienced before brings them to *the* thought, to *the* discovery, that other people are subsequently surprised they did not reach themselves, for they certainly can think afterwards, but they cannot think before. Thus the sun shone on all statues, but only the statue of Memnon gave forth a sound. For this reason Kant, Gœthe, and Jean Paul were highly sensitive to every noise, as their biographers bear witness.[13] Gœthe in his

last years bought a house which had fallen into disrepair close to his own, simply in order that he might not have to endure the noise that would be made in repairing it. Thus it was in vain that in his youth he followed the drum in order to harden himself against noise. It is not a matter of custom. On the other hand, the truly stoical indifference to noise of ordinary minds is astonishing. No noise disturbs them in their thinking, reading, writing, or other occupations, while the finer mind is rendered quite incapable by it. But just that which makes them so insensible to noise of every kind makes them also insensible to the beautiful in plastic art, and to deep thought or fine expression in literary art; in short, to all that does not touch their personal interests. The following remark of Lichtenberg's applies to the paralysing effect which noise has upon highly intellectual persons: "It is always a good sign when an artist can be hindered by trifles from exercising his art. F —— used to stick his fingers into sulphur if he wished to play the piano.... Such things do not interfere with the average mind;... it acts like a coarse sieve" (*Vermischte Schriften*, vol. i. p. 398). I have long really held the opinion that the amount of noise which any one can bear undisturbed stands in inverse proportion to his mental capacity, and therefore may be regarded as a pretty fair measure of it. Therefore, if I hear the dogs barking for hours together in the court of a house without being stopped, I know what to think of the intellectual capacity of the inhabitants. The man who habitually slams the door of a room, instead of shutting it with his hand, or allows this to go on in his house, is not only ill-bred, but is also a coarse and dull-minded fellow. That in English "sensible" also means gifted with understanding is based upon accurate and fine observation. We shall only become quite civilised when the ears are no longer unprotected, and when it shall no longer be the right of everybody to sever the consciousness of each thinking being, in its course of a thousand steps, with whistling, howling, bellowing, hammering, whip-cracking, barking, &c. &c. The Sybarites banished all noisy trades without the town; the honourable sect of the Shakers in North America permit no unnecessary noise in their villages, and the Moravians have a similar rule. Something more is said upon this subject in the thirtieth chapter of the second volume of the "Parerga."

The effect of music upon the mind, so penetrating, so direct, so unfailing, may be explained from the *passive* nature of hearing which has been discussed; also the after effect which sometimes follows it, and which consists in a specially elevated frame of mind. The vibrations of the tones

following in rationally combined numerical relations set the fibre of the brain itself in similar vibration. On the other hand, the *active* nature of sight, opposed as it is to the passive nature of hearing, makes it intelligible why there can be nothing analogous to music for the eye, and the piano of colours was an absurd mistake. Further, it is just on account of the active nature of the sense of sight that it is remarkably acute in the case of beasts that hunt, *i.e.*, beasts of prey, while conversely the *passive* sense of hearing is specially acute in those beasts that are hunted, that flee, and are timid, so that it may give them timely warning of the pursuer that is rushing or creeping upon them.

Just as we have recognised in sight the sense of the understanding, and in hearing the sense of the reason, so we might call smell the sense of the memory, because it recalls to us more directly than any other the specific impression of an event or a scene even from the most distant past.

Chapter IV. On Knowledge A Priori.

From the fact that we are able spontaneously to assign and determine the laws of relations in space without having recourse to experience, Plato concludes (*Meno*, p. 353, Bip.) that all learning is mere recollection. Kant, on the other hand, concludes that space is subjectively conditioned, and merely a form of the faculty of knowledge. How far, in this regard, does Kant stand above Plato!

Cogito, ergo sum, is an analytical judgment. Indeed Parmenides held it to be an identical judgment: "το γαρ αυτο νοειν εστι τε και ειναι" (*nam intelligere et esse idem est*, *Clem. Alex. Strom.*, vi. 2, § 23). As such, however, or indeed even as an analytical judgment, it cannot contain any special wisdom; nor yet if, to go still deeper, we seek to deduce it as a conclusion from the major premise, *non-entis nulla sunt prædicata*. But with this proposition what Descartes really wished to express was the great truth that immediate certainty belongs only to self-consciousness, to what is subjective. To what is objective, on the other hand, thus to everything else, only indirect certainty belongs; for it is arrived at through self-consciousness; and being thus merely at second hand, it is to be regarded as problematical. Upon this depends the value of this celebrated proposition. As its opposite we may set up, in the sense of the Kantian philosophy, *cogito, ergo est*, that is, exactly as I think certain relations in things (the mathematical), they must always occur in all possible experience; — this was an important, profound, and a late *apperçu*, which appeared in the form of the problem as to the *possibility of synthetic judgments a priori*, and has actually opened up the way to a deeper knowledge. This problem is the watchword of the Kantian philosophy, as the former proposition is that of the Cartesian, and shows εξ οἰων εισ οἰα.

Kant very fitly places his investigations concerning time and space at the head of all the rest. For to the speculative mind these questions present themselves before all others: what is time? — what is this that consists of mere movement, without anything that moves it? — and what is space? this omnipresent nothing, out of which nothing that exists can escape without ceasing to be anything at all?

That time and space depend on the subject, are the mode in which the process of objective apperception is brought about in the brain, has already

a sufficient proof in the absolute impossibility of thinking away time and space, while we can very easily think away everything that is presented in them. The hand can leave go of everything except itself. However, I wish here to illustrate by a few examples and deductions the more exact proofs of this truth which are given by Kant, not for the purpose of refuting stupid objections, but for the use of those who may have to expound Kant's doctrine in future.

"A right-angled equilateral triangle" contains no logical contradiction; for the predicates do not by any means cancel the subject, nor are they inconsistent with each other. It is only when their object is constructed in pure perception that the impossibility of their union in it appears. Now if on this account we were to regard this as a contradiction, then so would every physical impossibility, only discovered to be such after the lapse of centuries, be a contradiction; for example, the composition of a metal from its elements, or a mammal with more or fewer than seven cervical vertebra,[14] or horns and upper incisors in the same animal. But only *logical* impossibility is a contradiction, not physical, and just as little mathematical. Equilateral and rectangled do not contradict each other (they coexist in the square), nor does either of them contradict a triangle. Therefore the incompatibility of the above conceptions can never be known by mere *thinking*, but is only discovered by perception — merely mental perception, however, which requires no experience, no real object. We should also refer here to the proposition of Giordano Bruno, which is also found in Aristotle: "An infinitely large body is necessarily immovable" — a proposition which cannot rest either upon experience or upon the principle of contradiction, since it speaks of things which cannot occur in any experience, and the conceptions "infinitely large" and "movable" do not contradict each other; but it is only pure perception that informs us that motion demands a space outside the body, while its infinite size leaves no space over. Suppose, now, it should be objected to the first mathematical example that it is only a question of how complete a conception of a triangle the person judging has: if the conception is quite complete it will also contain the impossibility of a triangle being rectangular and also equilateral. The answer to this is: assume that his conception is not so complete, yet without recourse to experience he can, by the mere construction of the triangle in his imagination, extend his conception of it and convince himself for ever of the impossibility of this combination of these conceptions. This process, however, is a synthetic

judgment *a priori*, that is, a judgment through which, independently of all experience, and yet with validity for all experience, we form and perfect our conceptions. For, in general, whether a given judgment is analytical or synthetical can only be determined in the particular case according as the conception of the subject in the mind of the person judging is more or less complete. The conception "cat" contains in the mind of a Cuvier a hundred times more than in that of his servant; therefore the same judgments about it will be synthetical for the latter, and only analytical for the former. But if we take the conceptions objectively, and now wish to decide whether a given judgment is analytical or synthetical, we must change the predicate into its contradictory opposite, and apply this to the subject without a copula. If this gives a *contradictio in adjecto*, then the judgment was analytical; otherwise it was synthetical.

That Arithmetic rests on the pure intuition or perception of time is not so evident as that Geometry is based upon that of space.[15] It can be proved, however, in the following manner. All counting consists in the repeated affirmation of unity. Only for the purpose of always knowing how often we have already affirmed unity do we mark it each time with another word: these are the numerals. Now repetition is only possible through succession. But succession, that is, being after one another, depends directly upon the intuition or perception of *time*. It is a conception which can only be understood by means of this; and thus counting also is only possible by means of time. This dependence of all counting upon time is also betrayed by the fact that in all languages multiplication is expressed by "time," thus by a time-concept: *sexies*, ἑξακις, *six fois*, *sex mal*. But simple counting is already a multiplication by one, and for this reason in Pestalozzi's educational establishment the children are always made to multiply thus: "Two times two is four times one." Aristotle already recognised the close relationship of number and time, and expounded it in the fourteenth chapter of the fourth book of the "Physics." Time is for him "the number of motion" ("ὁ χρονος αριθμος εστι κινησεως"). He very profoundly suggests the question whether time could be if the soul were not, and answers it in the negative. If arithmetic had not this pure intuition or perception of time at its foundation, it would be no science *a priori*, and therefore its propositions would not have infallible certainty.

Although time, like space, is the form of knowledge of the subject, yet, just like space, it presents itself as independent of the subject and

completely objective. Against our will, or without our knowledge, it goes fast or slow. We ask what o'clock it is; we investigate time, as if it were something quite objective. And what is this objective existence? Not the progress of the stars, or of the clocks, which merely serve to measure the course of time itself, but it is something different from all things, and yet, like them, independent of our will and knowledge. It exists only in the heads of percipient beings, but the uniformity of its course and its independence of the will give it the authority of objectivity.

Time is primarily the form of inner sense. Anticipating the following book, I remark that the only object of inner sense is the individual will of the knowing subject. Time is therefore the form by means of which self-consciousness becomes possible for the individual will, which originally and in itself is without knowledge. In it the nature of the will, which in itself is simple and identical, appears drawn out into a course of life. But just on account of this original simplicity and identity of what thus exhibits itself, its *character* remains always precisely the same, and hence also the course of life itself retains throughout the same key-note, indeed its multifarious events and scenes are at bottom just like variations of one and the same theme.

The *a priori nature of the law of causality* has, by Englishmen and Frenchmen, sometimes not been seen at all, sometimes not rightly conceived of; and therefore some of them still prosecute the earlier attempts to find for it an *empirical* origin. Maine de Biran places this in the experience that the act of will as cause is followed by the movement of the body as effect. But this fact itself is untrue. We certainly do not recognise the really immediate act of will as something different from the action of the body, and the two as connected by the bond of causality; but both are one and indivisible. Between them there is no succession; they are simultaneous. They are one and the same thing, apprehended in a double manner. That which makes itself known to inner apprehension (self-consciousness) as the real *act of will* exhibits itself at once in external perception, in which the body exists objectively as an *action* of the body. That physiologically the action of the nerve precedes that of the muscle is here immaterial, for it does not come within self-consciousness; and we are not speaking here of the relation between muscle and nerve, but of that between the act of will and the action of the body. Now this does not present itself as a causal relation. If these two presented themselves to us as

cause and effect their connection would not be so incomprehensible to us as it actually is; for what we understand from its cause we understand as far as there is an understanding of things generally. On the other hand, the movement of our limbs by means of mere acts of will is indeed a miracle of such common occurrence that we no longer observe it; but if we once turn our attention to it we become keenly conscious of the incomprehensibility of the matter, just because in this we have something before us which we do *not* understand as the effect of a cause. This apprehension, then, could never lead us to the idea of causality, for that never appears in it at all. Maine de Biran himself recognises the perfect simultaneousness of the act of will and the movement (*Nouvelles Considérations des Rapports du Physique au Moral*, p. 377, 378). In England Thomas Reid (On the First Principles of Contingent Truths, Essay IV. c. 5) already asserted that the knowledge of the causal relation has its ground in the nature of the faculty of knowledge itself. Quite recently Thomas Brown, in his very tediously composed book, "Inquiry into the Relation of Cause and Effect," 4th edit., 1835, says much the same thing, that that knowledge springs from an innate, intuitive, and instinctive conviction; thus he is at bottom upon the right path. Quite unpardonable, however, is the crass ignorance on account of which in this book of 476 pages, of which 130 are devoted to the refutation of Hume, absolutely no mention is made of Kant, who cleared up the question more than seventy years ago. If Latin had remained the exclusive language of science such a thing would not have occurred. In spite of Brown's exposition, which in the main is correct, a modification of the doctrine set up by Maine de Biran, of the empirical origin of the fundamental knowledge of the causal relation, has yet found acceptance in England; for it is not without a certain degree of plausibility. It is this, that we abstract the law of causality from the perceived effect of our own body upon other bodies. This was already refuted by Hume. I, however, have shown that it is untenable in my work, "*Ueber den Willen in der Natur*" (p. 75 of the second edition, p. 82 of the third), from the fact that since we apprehend both our own and other bodies objectively in spatial perception, the knowledge of causality must already be there, because it is a condition of such perception. The one genuine proof that we are conscious of the law of causality *before all experience* lies in the necessity of making a *transition* from the sensation, which is only empirically given, to its *cause*, in order that it may become perception of the external world. Therefore I have

substituted this proof for the Kantian, the incorrectness of which I have shown. A most full and thorough exposition of the whole of this important subject, which is only touched on here, the *a priori* nature of the law of causality and the intellectual nature of empirical perception, will be found in my essay on the principle of sufficient reason, § 21, to which I refer, in order to avoid the necessity of repeating here what is said there. I have also shown there the enormous difference between the mere sensation of the senses and the perception of an objective world, and discovered the wide gulf that lies between the two. The law of causality alone can bridge across this gulf, and it presupposes for its application the two other forms which are related to it, space and time. Only by means of these three combined is the objective idea attained to. Now whether the sensation from which we start to arrive at apprehension arises through the resistance which is suffered by our muscular exertion, or through the impression of light upon the retina, or of sound upon the nerves of the brain, &c. &c., is really a matter of indifference. The *sensation* always remains a mere *datum* for the *understanding*, which alone is capable of apprehending it as the effect of a cause different from itself, which the understanding now perceives as external, *i.e.*, as something occupying and filling space, which is also a form inherent in the intellect prior to all experience. Without this intellectual operation, for which the forms must lie ready in us, the perception of an *objective, external world* could never arise from a mere *sensation* within our skin. How can it ever be supposed that the mere feeling of being hindered in intended motion, which occurs also in lameness, could be sufficient for this? We may add to this that before I attempt to affect external things *they* must necessarily have affected me as motives. But this almost presupposes the apprehension of the external world. According to the theory in question (as I have remarked in the place referred to above), a man born without arms and legs could never attain to the idea of causality, and consequently could never arrive at the apprehension of the external world. But that this is not the case is proved by a fact communicated in Froriep's *Notizen*, July 1838, No. 133 — the detailed account, accompanied by a likeness, of an Esthonian girl, Eva Lauk, then fourteen years old, who was born entirely without arms or legs. The account concludes with these words: "According to the evidence of her mother, her mental development had been quite as quick as that of her brothers and sisters; she attained just as soon as they did to a correct

judgment of size and distance, yet without the assistance of hands. — Dorpat, 1st March 1838, Dr. A. Hueck.”

Hume’s doctrine also, that the conception of causality arises from the custom of seeing two states constantly following each other, finds a practical refutation in the oldest of all successions, that of day and night, which no one has ever held to be cause and effect of each other. And the same succession also refutes Kant’s false assertion that the *objective* reality of a succession is only known when we apprehend the two succeeding events as standing in the relation of cause and effect to each other. Indeed the converse of this doctrine of Kant’s is true. We know which of the two connected events is the cause and which the effect, *empirically*, only in the succession. Again, on the other hand, the absurd assertion of several professors of philosophy in our own day that cause and effect are simultaneous can be refuted by the fact that in cases in which the succession cannot be perceived on account of its great rapidity, we yet assume it with certainty *a priori*, and with it the lapse of a certain time. Thus, for example, we know that a certain time must elapse between the falling of the flint and the projection of the bullet, although we cannot perceive it, and that this time must further be divided between several events that occur in a strictly determined succession — the falling of the flint, the striking of the spark, ignition, the spread of the fire, the explosion, and the projection of the bullet. No man ever perceived this succession of events; but because we know which is the cause of the others, we thereby also know which must *precede the others in time*, and consequently also that during the course of the whole series a certain time must elapse, although it is so short that it escapes our empirical apprehension; for no one will assert that the projection of the bullet is actually simultaneous with the falling of the flint. Thus not only the law of causality, but also its relation to *time*, and the necessity of the *succession* of cause and effect, is known to us *a priori*. If we know which of two events is the cause and which is the effect, we also know which precedes the other in time; if, on the contrary, we do not know which is cause and which effect, but only know in general that they are causally connected, we seek to discover the succession empirically, and according to that we determine which is the cause and which the effect. The falseness of the assertion that cause and effect are simultaneous further appears from the following consideration. An unbroken chain of causes and effects fills the whole of time. (For if this chain were broken the world

would stand still, or in order to set it in motion again an effect without a cause would have to appear.) Now if every effect were simultaneous with its cause, then every effect would be moved up into the time of its cause, and a chain of causes and effects containing as many links as before would fill no time at all, still less an infinite time, but would be all together in one moment. Thus, under the assumption that cause and effect are simultaneous, the course of the world shrinks up into an affair of a moment. This proof is analogous to the proof that every sheet of paper must have a certain thickness, because otherwise the whole book would have none. To say *when* the cause ceases and the effect begins is in almost all cases difficult, and often impossible. For the *changes* (*i.e.*, the succession of states) are continuous, like the time which they fill, and therefore also, like it, they are infinitely divisible. But their succession is as necessarily determined and as unmistakable as that of the moments of time itself, and each of them is called, with reference to the one which precedes it, "effect," and with reference to the one which follows it, "cause."

Every change in the material world can only take place because another has immediately preceded it: this is the true and the whole content of the law of causality. But no conception has been more misused in philosophy than that of *cause*, by means of the favourite trick or blunder of conceiving it too widely, taking it too generally, through abstract thinking. Since Scholasticism, indeed properly since Plato and Aristotle, philosophy has been for the most part a *systematic misuse of general conceptions*. Such, for example, are substance, ground, cause, the good, perfection, necessity, and very many others. A tendency of the mind to work with such abstract and too widely comprehended conceptions has shown itself almost at all times. It may ultimately rest upon a certain indolence of the intellect, which finds it too difficult a task to be constantly controlling thought by perception. By degrees such unduly wide conceptions come to be used almost like algebraical symbols, and tossed about like them, and thus philosophy is reduced to a mere process of combination, a kind of reckoning which (like all calculations) employs and demands only the lower faculties. Indeed there finally results from this a mere juggling with words, of which the most shocking example is afforded us by the mind-destroying Hegelism, in which it is carried to the extent of pure nonsense. But Scholasticism also often degenerated into word-juggling. Nay even the "Topi" of Aristotle — very abstract principles, conceived with absolute generality, which one could

apply to the most different kinds of subjects, and always bring into the field in arguing either *pro* or *contra* — have also their origin in this misuse of general conceptions. We find innumerable examples of the way the Schoolmen worked with such abstractions in their writings, especially in those of Thomas Aquinas. But philosophy really pursued the path which was entered on by the Schoolmen down to the time of Locke and Kant, who at last bethought themselves as to the origin of conceptions. Indeed we find Kant himself, in his earlier years, still upon that path, in his "Proof of the Existence of God" (p. 191 of the first volume of Rosenkranz's edition), where the conceptions substance, ground, reality, are used in such a way as would never have been possible if he had gone back to the *source* of these conceptions and to their *true content* which is determined thereby. For then he would have found as the source and content of *substance* simply matter, of ground (if things of the real world are in question) simply cause, that is, the prior change which brings about the later change, &c. It is true that in this case such an investigation would not have led to the intended result. But everywhere, as here, such unduly wide conceptions, under which, therefore, more was subsumed than their true content would have justified, there have arisen false principles, and from these false systems. Spinoza's whole method of demonstration rests upon such uninvestigated and too widely comprehended conceptions. Now here lies the great merit of Locke, who, in order to counteract all that dogmatic unreality, insisted upon the investigation of the *origin of the conceptions*, and thus led back to *perception and experience*. Bacon had worked in a similar frame of mind, yet more with reference to Physics than to Metaphysics. Kant followed the path entered upon by Locke, but in a higher sense and much further, as has already been mentioned above. To the men of mere show who succeeded in diverting the attention of the public from Kant to themselves the results obtained by Locke and Kant were inconvenient. But in such a case they know how to ignore both the dead and the living. Thus without hesitation they forsook the only right path which had at last been found by those wise men, and philosophised at random with all kinds of indiscriminately collected conceptions, unconcerned as to their origin and content, till at last the substance of the Hegelian philosophy, wise beyond measure, was that the conceptions had no origin at all, but were rather themselves the origin and source of things. But Kant has erred in this respect. He has too much neglected empirical perception for the sake of *pure* perception — a point

which I have fully discussed in my criticism of his philosophy. With me perception is throughout the source of all knowledge. I early recognised the misleading and insidious nature of abstractions, and in 1813, in my essay on the principle of sufficient reason, I pointed out the difference of the relations which are thought under *this* conception. General conceptions must indeed be the material in which philosophy deposits and stores up its knowledge, but not the source from which it draws it; the *terminus ad quem*, not *a quo*. It is not, as Kant defines it, a science *drawn from* conceptions, but a science *in* conceptions. Thus the conception of causality also, with which we are here concerned, has always been taken far too widely by philosophers for the furtherance of their dogmatic ends, and much was imported into it which does not belong to it at all. Hence arose propositions such as the following: "All that is has its cause"— "the effect cannot contain more than the cause, thus nothing that was not also in the cause"— "*causa est nobilior suo effectu*," and many others just as unwarranted. The following subtilty of that insipid gossip Proclus affords an elaborate and specially lucid example of this. It occurs in his "*Institutio Theologica*," § 76: "Παν το απο ακινητου γιγνομενον αιτιας, αμεταβλητον εχει την ὑπαρξιν; παν δε το απο κινουμενης, μεταβλητην; ει γαρ ακινητον εστι παντῃ το ποιουν, ου δια κινησεως, αλλ᾽ αυτῳ τῳ ειναι παραγει το δευτερον αφ᾽ ἑαυτου." (*Quidquid ab immobili causa manat, immutabilem habet essentiam [substantiam]. Quidquid vero a mobili causa manat, essentiam habet mutabilem. Si enim illud, quod aliquid facit, est prorsus immobile, non per motum, sed per ipsum Esse producit ipsum secundum ex se ipso.*) Excellent! But just show me a cause which is not itself set in motion: it is simply impossible. But here, as in so many cases, abstraction has thought away all determinations down to that one which it is desired to make use of without regard to the fact that the latter cannot exist without the former. The only correct expression of the law of causality is this: *Every change has its cause in another change which immediately precedes it*. If something *happens*, *i.e.*, if a new state of things appears, *i.e.*, if something is *changed*, then something else must have *changed* immediately before, and something else again before this, and so on *ad infinitum*, for a *first* cause is as impossible to conceive as a beginning of time or a limit of space. More than this the law of causality does not assert. Thus its claims only arise in the case of *changes*. So long as nothing changes there can be no question of

a cause. For there is no *a priori* ground for inferring from the existence of given things, *i.e.*, states of matter, their previous non-existence, and from this again their coming into being, that is to say, there is no *a priori* ground for inferring a change. Therefore the mere existence of a thing does not justify us in inferring that it has a cause. Yet there may be *a posteriori* reasons, that is, reasons drawn from previous experience, for the assumption that the present state or condition did not always exist, but has only come into existence in consequence of another state, and therefore by means of a change, the cause of which is then to be sought, and also the cause of this cause. Here then we are involved in the *infinite regressus* to which the application of the law of causality always leads. We said above: "*Things*, *i.e.*, *states or conditions of matter,*" for *change* and *causality* have only to do with states or conditions. It is these states which we understand by *form*, in the wider sense; and only the forms change, the matter is permanent. Thus it is only the form which is subject to the law of causality. But the form constitutes the *thing*, *i.e.*, it is the ground of *the difference* of things; while matter must be thought as the same in all. Therefore the Schoolmen said, "*Forma dat esse rei;*" more accurately this proposition would run: *Forma dat rei essentiam, materia existentiam*. Therefore the question as to the cause of a *thing* always concerns merely its form, *i.e.*, its state or quality, and not its matter, and indeed only the former so far as we have grounds for assuming that it has not *always* existed, but has come into being by means of a *change*. The union of *form* and *matter*, or of *essentia* and *existentia*, gives the *concrete*, which is always particular; thus, the *thing*. And it is the *forms* whose union with *matter*, *i.e.*, whose appearance in matter by means of a *change*, are subject to the law of causality. By taking the conception *too widely* in the abstract the mistake slipped in of extending causality to the thing absolutely, that is, to its whole inner nature and existence, thus also to matter, and ultimately it was thought justifiable to ask for a cause of the world itself. This is the origin of the *cosmological proof*. This proof begins by inferring from the existence of the world its non-existence, which preceded its existence, and such an inference is quite unjustifiable; it ends, however, with the most fearful inconsistency, for it does away altogether with the law of causality, from which alone it derives all its evidencing power, for it stops at a first cause, and will not go further; thus ends, as it were, by committing parricide, as the bees kill the drones

after they have served their end. All the talk about the *absolute* is referable to a shamefast, and therefore disguised cosmological proof, which, in the face of the "Critique of Pure Reason," has passed for philosophy in Germany for the last sixty years. What does the absolute mean? Something that is, and of which (under pain of punishment) we dare not ask further whence and why it is. A precious rarity for professors of philosophy! In the case, however, of the honestly expressed cosmological proof, through the assumption of a first cause, and therefore of a first beginning in a time which has absolutely no beginning, this beginning is always pushed further back by the question: Why not earlier? And so far back indeed that one never gets down from it to the present, but is always marvelling that the present itself did not occur already millions of years ago. In general, then, the law of causality applies to all things in the world, but not to the world itself, for it is *immanent* in the world, not *transcendent; with* it it comes into action, and *with* it it is abolished. This depends ultimately upon the fact that it belongs to the mere form of our understanding, like the whole of the objective world, which accordingly is merely phenomenal, and is conditioned by the understanding. Thus the law of causality has full application, without any exception, to all things in the world, of course in respect of their form, to the variation of these forms, and thus to their changes. It is valid for the actions of men as for the impact of a stone, yet, as we have said always, merely with regard to events, to *changes*. But if we abstract from its origin in the understanding and try to look at it as purely objective, it will be found in ultimate analysis to depend upon the fact that everything that acts does so by virtue of its original, and therefore eternal or timeless, power; therefore its present effect would necessarily have occurred infinitely earlier, that is, before all conceivable time, but that it lacked the temporal condition. This temporal condition is the occasion, *i.e.*, the cause, on account of which alone the effect only takes place *now*, but now takes place necessarily; the cause assigns it its place in time.

But in consequence of that unduly wide view in abstract thought of the conception *cause*, which was considered above, it has been confounded with the conception of *force*. This is something completely different from the cause, but yet is that which imparts to every cause its causality, *i.e.*, the capability of producing an effect. I have explained this fully and thoroughly in the second book of the first volume, also in "The Will in Nature," and

finally also in the second edition of the essay on the principle of sufficient reason, § 20, p. 44 (third edition, p. 45). This confusion is to be found in its most aggravated form in Maine de Biran's book mentioned above, and this is dealt with more fully in the place last referred to; but apart from this it is also very common; for example, when people seek for the cause of any original force, such as gravitation. Kant himself (*Über den Einzig Möglichen Beweisgrund*, vol. i. p. 211-215 of Rosenkranz's edition) calls the forces of nature "efficient causes," and says "gravity is a cause." Yet it is impossible to see to the bottom of his thought so long as force and cause are not distinctly recognised as completely different. But the use of abstract conceptions leads very easily to their confusion if the consideration of their origin is set aside. The knowledge of causes and effects, always *perceptive*, which rests on the form of the understanding, is neglected in order to stick to the abstraction *cause*. In this way alone is the conception of causality, with all its simplicity, so very frequently wrongly apprehended. Therefore even in Aristotle ("Metaph.," iv. 2) we find causes divided into four classes which are utterly falsely, and indeed crudely conceived. Compare with it my classification of causes as set forth for the first time in my essay on sight and colour, chap. 1, and touched upon briefly in the sixth paragraph of the first volume of the present work, but expounded at full length in my prize essay on the freedom of the will, p. 30-33. Two things in nature remain untouched by that chain of causality which stretches into infinity in both directions; these are matter and the forces of nature. They are both conditions of causality, while everything else is conditioned by it. For the one (matter) is that *in* which the states and their changes appear; the other (forces of nature) is that by virtue of which alone they can appear at all. Here, however, one must remember that in the second book, and later and more thoroughly in "The Will in Nature," the natural forces are shown to be identical with the will in us; but matter appears as the mere *visibility of the will*; so that ultimately it also may in a certain sense be regarded as identical with the will.

On the other hand, not less true and correct is what is explained in § 4 of the first book, and still better in the second edition of the essay on the principle of sufficient reason at the end of § 21, p. 77 (third edition, p. 82), that matter is causality itself objectively comprehended, for its entire nature consists in *acting in general*, so that it itself is thus the activity (ενεργεια = reality) of things generally, as it were the abstraction of all their different

kinds of acting. Accordingly, since the essence, *essentia*, of matter consists in *action in general*, and the reality, *existentia*, of things consists in their materiality, which thus again is one with action in general, it may be asserted of matter that in it *existentia* and *essentia* unite and are one, for it has no other attribute than *existence itself* in general and independent of all fuller definitions of it. On the other hand, all *empirically* given matter, thus all material or matter in the special sense (which our ignorant materialists at the present day confound with matter), has already entered the framework of the *forms* and manifests itself only through their qualities and accidents, because in experience every action is of quite a definite and special kind, and is never merely general. Therefore pure matter is an object of *thought* alone, not of *perception*, which led Plotinus (*Enneas II.*, lib. iv., c. 8 & 9) and Giordano Bruno (*Della Causa*, dial. 4) to make the paradoxical assertion that matter has no extension, for extension is inseparable from the form, and that therefore it is *incorporeal*. Yet Aristotle had already taught that it is not a body although it is corporeal: "σωμα μεν ουκ αν ειη, σωματικη δε" (*Stob. Ecl.*, lib. i., c. 12, § 5). In reality we think under *pure matter* only action, in the abstract, quite independent of the *kind* of action, thus *pure causality* itself; and as such it is not an *object* but a *condition* of experience, just like space and time. This is the reason why in the accompanying table of our pure *a priori* knowledge matter is able to take the place of causality, and therefore appears along with space and time as the third pure form, and therefore as dependent on our intellect.

This table contains all the fundamental truths which are rooted in our perceptive or intuitive knowledge *a priori*, expressed as first principles independent of each other. What is special, however, what forms the content of arithmetic and geometry, is not given here, nor yet what only results from the union and application of those formal principles of knowledge. This is the subject of the "Metaphysical First Principles of Natural Science" expounded by Kant, to which this table in some measure forms the propædutic and introduction, and with which it therefore stands in direct connection. In this table I have primarily had in view the very remarkable *parallelism* of those *a priori* principles of knowledge which form the framework of all experience, but specially also the fact that, as I have explained in § 4 of the first volume, matter (and also causality) is to be regarded as a combination, or if it is preferred, an amalgamation, of space

and time. In agreement with this, we find that what geometry is for the pure perception or intuition of space, and arithmetic for that of time, Kant's *phoronomy* is for the pure perception or intuition of the two *united*. For matter is primarily that which is movable in space. The mathematical point cannot even be conceived as movable, as Aristotle has shown ("Physics," vi. 10). This philosopher also himself provided the first example of such a science, for in the fifth and sixth books of his "Physics" he determined *a priori* the laws of rest and motion.

Now this table may be regarded at pleasure either as a collection of the eternal laws of the world, and therefore as the basis of our ontology, or as a chapter of the physiology of the brain, according as one assumes the realistic or the idealistic point of view; but the second is in the last instance right. On this point, indeed, we have already come to an understanding in the first chapter; yet I wish further to illustrate it specially by an example. Aristotle's book "*De Xenophane*," &c., commences with these weighty words of Xenophanes: "Αϊδιον ειναι φησιν, ει τι εστιν, ειπερ μη ενδεχεται γενεσθαι μηδεν εκ μηδενος." (*Æternum esse, inquit, quicquid est, siquidem fieri non potest, ut ex nihilo quippiam existat.*) Here, then, Xenophanes judges as to the origin of things, as regards its possibility, and of this origin he can have had no experience, even by analogy; nor indeed does he appeal to experience, but judges apodictically, and therefore *a priori*. How can he do this if as a stranger he looks from without into a world that exists purely objectively, that is, independently of his knowledge? How can he, an ephemeral being hurrying past, to whom only a hasty glance into such a world is permitted, judge apodictically, *a priori* and without experience concerning that world, the possibility of its existence and origin? The solution of this riddle is that the man has only to do with his own ideas, which as such are the work of his brain, and the constitution of which is merely the manner or mode in which alone the function of his brain can be fulfilled, *i.e.*, the form of his perception. He thus judges only as to the *phenomena of his own brain*, and declares what enters into its forms, time, space, and causality, and what does not. In this he is perfectly at home and speaks apodictically. In a like sense, then, the following table of the *Prædicabilia a priori* of time, space, and matter is to be taken: —

Prædicabilia *A Priori*.

Of Time.	Of Space.	Of Matter.

(1) There is only *one* Time, and all different times are parts of it.	(1) There is only *one* Space, and all different spaces are parts of it.	(1) There is only *one* Matter, and all different materials are different states of matter; as such it is called *Substance*.
(2) Different times are not simultaneous but successive.	(2) Different spaces are not successive but simultaneous.	(2) Different matters (materials) are not so through substance but through accidents.
(3) Time cannot be thought away, but everything can be thought away from it.	(3) Space cannot be thought away, but everything can be thought away from it.	(3) Annihilation of matter is inconceivable, but annihilation of all its forms and qualities is conceivable.
(4) Time has three divisions, the past, the present, and the future, which constitute two directions and a centre of indifference.	(4) Space has three dimensions — height, breadth, and length.	(4) Matter exists, *i.e.*, acts in all the dimensions of space and throughout the whole length of time, and thus these two are united and thereby filled. In this consists the true nature of matter; thus it is through and through causality.
(5) Time is infinitely divisible.	(5) Space is infinitely divisible.	(5) Matter is infinitely divisible.
(6) Time is homogeneous and a *Continuum*, *i.e.*, no one of its parts is different from the rest, nor separated from it by anything that is not time.	(6) Space is homogeneous and a *Continuum*, *i.e.*, no one of its parts is different from the rest, nor separated from it by anything that is not space.	(6) Matter is homogeneous and a *Continuum*, *i.e.*, it does not consist of originally different (*homoiomeria*) or originally separated parts (atoms); it is therefore not composed of parts, which would necessarily be separated by something that was not matter.

(7) Time has no beginning and no end, but all beginning and end is in it.	(7) Space has no limits, but all limits are in it.	(7) Matter has no origin and no end, but all coming into being and passing away are in it.
(8) By reason of time we count.	(8) By reason of space we measure.	(8) By reason of matter we weigh.
(9) Rhythm is only in time.	(9) Symmetry is only in space.	(9) Equilibrium is only in matter.
(10) We know the laws of time *a priori*.	(10) We know the laws of space *a priori*.	(10) We know the laws of the substance of all accidents *a priori*.
(11) Time can be perceived *a priori*, although only in the form of a line.	(11) Space is immediately perceptible *a priori*.	(11) Matter can only be thought *a priori*.
(12) Time has no permanence, but passes away as soon as it is there.	(12) Space can never pass away, but endures through all time.	(12) The accidents change; the substance remains.
(13) Time never rests.	(13) Space is immovable.	(13) Matter is indifferent to rest and motion, *i.e.*, it is originally disposed towards neither of the two.
(14) Everything that exists in time has duration.	(14) Everything that exists in space has a position.	(14) Everything material has the capacity for action.
(15) Time has no duration, but all duration is in it, and is the persistence of what is permanent in contrast with its restless course.	(15) Space has no motion, but all motion is in it, and it is the change of position of what is moved, in contrast with its unbroken rest.	(15) Matter is what is permanent in time and movable in space; by the comparison of what rests with what is moved we measure duration.
(16) All motion is only possible in	(16) All motion is only possible in space.	(16) All motion is only possible to matter.

time.		
(17) Velocity is, in equal spaces, in inverse proportion to the time.	(17) Velocity is, in equal times, in direct proportion to the space.	(17) The magnitude of the motion, the velocity being equal, is in direct geometrical proportion to the matter (mass).
(18) Time is not measurable directly through itself, but only indirectly through motion, which is in space and time together: thus the motion of the sun and of the clock measure time.	(18) Space is measurable directly through itself, and indirectly through motion, which is in time and space together; hence, for example, an hour's journey, and the distance of the fixed stars expressed as the travelling of light for so many years.	(18) Matter as such (mass) is measurable, *i.e.*, determinable as regards its quantity only indirectly, only through the amount of the motion which it receives and imparts when it is repelled or attracted.
(19) Time is omnipresent. Every part of time is everywhere, *i.e.*, in all space, at once.	(19) Space is eternal. Every part of it exists always.	(19) Matter is absolute. That is, it neither comes into being nor passes away, and thus its quantity can neither be increased nor diminished.
(20) In time taken by itself everything would be in succession.	(20) In space taken by itself everything would be simultaneous.	(20, 21) Matter unites the ceaseless flight of time with the rigid immobility of space; therefore it is the permanent substance of the changing accidents. Causality determines this change for every place at every time, and thereby combines time and space, and constitutes the whole nature of matter.
(21) Time makes the change of accidents possible.	(21) Space makes the permanence of substance possible.	

(22) Every part of time contains all parts of matter.	(22) No part of space contains the same matter as another.	(22) For matter is both permanent and impenetrable.
(23) Time is the *principium individuationis*.	(23) Space is the *principium individuationis*.	(23) Individuals are material.
(24) The now has no duration.	(24) The point has no extension.	(24) The atom has no reality.
(25) Time in itself is empty and without properties.	(25) Space in itself is empty and without properties.	(25) Matter in itself is without form and quality, and likewise inert, *i.e.*, indifferent to rest or motion, thus without properties.
(26) Every moment is conditioned by the preceding moment, and is only because the latter has ceased to be. (Principle of sufficient reason of existence in time. — See my essay on the principle of sufficient reason.)	(26) By the position of every limit in space with reference to any other limit, its position with reference to every possible limit is precisely determined. (Principle of sufficient reason of existence in space.)	(26) Every change in matter can take place only on account of another change which preceded it; and therefore a first change, and thus also a first state of matter, is just as inconceivable as a beginning of time or a limit of space. (Principle of sufficient reason of becoming.)
(27) Time makes arithmetic possible.	(27) Space makes geometry possible.	(27) Matter, as that which is movable in space, makes phoronomy possible.
(28) The simple element in arithmetic is unity.	(28) The simple element in geometry is the point.	(28) The simple element in phoronomy is the atom.

Notes to the Annexed Table.

(1) To No. 4 of Matter.

The essence of matter is acting, it is acting itself, in the abstract, thus acting in general apart from all difference of the kind of action: it is through and through causality. On this account it is itself, as regards its existence, not subject to the law of causality, and thus has neither come into being nor passes away, for otherwise the law of causality would be applied to itself. Since now causality is known to us *a priori*, the conception of matter, as the indestructible basis of all that exists, can so far take its place in the knowledge we possess *a priori*, inasmuch as it is only the realisation of an *a priori* form of our knowledge. For as soon as we see anything that acts or is causally efficient it presents itself *eo ipso* as material, and conversely anything material presents itself as necessarily active or causally efficient. They are in fact interchangeable conceptions. Therefore the word "actual" is used as synonymous with "material;" and also the Greek κατʹ ενεργειαν, in opposition to κατα δυναμιν, reveals the same source, for ενεργεια signifies action in general; so also with *actu* in opposition to *potentia*, and the English "actually" for "*wirklich*." What is called space-occupation, or impenetrability, and regarded as the essential predicate of body (*i.e.* of what is material), is merely that *kind of action* which belongs to *all* bodies without exception, the mechanical. It is this universality alone, by virtue of which it belongs to the conception of body, and follows *a priori* from this conception, and therefore cannot be thought away from it without doing away with the conception itself — it is this, I say, that distinguishes it from any other kind of action, such as that of electricity or chemistry, or light or heat. Kant has very accurately analysed this space-occupation of the mechanical mode of activity into repulsive and attractive force, just as a given mechanical force is analysed into two others by means of the parallelogram of forces. But this is really only the thoughtful analysis of the phenomenon into its two constituent parts. The two forces in conjunction exhibit the body within its own limits, that is, in a definite volume, while the one alone would diffuse it into infinity, and the other alone would contract it to a point. Notwithstanding this reciprocal balancing or neutralisation, the body still acts upon other bodies which contest its space with the first force, repelling them, and with the other force, in gravitation, attracting all bodies in general. So that the two forces are not extinguished in their product, as, for instance, two equal forces acting in different

directions, or +E and -E, or oxygen and hydrogen in water. That impenetrability and gravity really exactly coincide is shown by their empirical inseparableness, in that the one never appears without the other, although we can separate them in thought.

I must not, however, omit to mention that the doctrine of Kant referred to, which forms the fundamental thought of the second part of his "Metaphysical First Principles of Natural Science," thus of the Dynamics, was distinctly and fully expounded before Kant by Priestley, in his excellent "Disquisitions on Matter and Spirit," § 1 and 2, a book which appeared in 1777, and the second edition in 1782, while Kant's work was published in 1786. Unconscious recollection may certainly be assumed in the case of subsidiary thoughts, flashes of wit, comparisons, &c., but not in the case of the principal and fundamental thought. Shall we then believe that Kant silently appropriated such important thoughts of another man? and this from a book which at that time was new? Or that this book was unknown to him, and that the same thoughts sprang up in two minds within a short time? The explanation, also, which Kant gives, in the "Metaphysical First Principles of Natural Science" (first edition, p. 88; Rosenkranz's edition, p. 384), of the real difference between fluids and solids, is in substance already to be found in Kaspar Freidr. Wolff's "Theory of Generation," Berlin 1764, p. 132. But what are we to say if we find Kant's most important and brilliant doctrine, that of the ideality of space and the merely phenomenal existence of the corporeal world, already expressed by Maupertuis thirty years earlier? This will be found more fully referred to in Frauenstädt's letters on my philosophy, Letter 14. Maupertuis expresses this paradoxical doctrine so decidedly, and yet without adducing any proof of it, that one must suppose that he also took it from somewhere else. It is very desirable that the matter should be further investigated, and as this would demand tiresome and extensive researches, some German Academy might very well make the question the subject of a prize essay. Now in the same relation as that in which Kant here stands to Priestley, and perhaps also to Kaspar Wolff, and Maupertuis or his predecessor, Laplace stands to Kant. For the principal and fundamental thought of Laplace's admirable and certainly correct theory of the origin of the planetary system, which is set forth in his "*Exposition du Système du Monde*," liv. v. c. 2, was expressed by Kant nearly fifty years before, in 1755, in his "*Naturgeschichte und Theorie des Himmels*," and more fully in 1763 in his "*Einzig möglichen Beweisgrund des Daseyns*

Gottes," ch. 7. Moreover, in the later work he gives us to understand that Lambert in his "*Kosmologischen Briefen*," 1761, tacitly adopted that doctrine from him, and these letters at the same time also appeared in French (*Lettres Cosmologiques sur la Constitution de l'Univers*). We are therefore obliged to assume that Laplace knew that Kantian doctrine. Certainly he expounds the matter more thoroughly, strikingly, and fully, and at the same time more simply than Kant, as is natural from his more profound astronomical knowledge; yet in the main it is to be found clearly expressed in Kant, and on account of the importance of the matter, would alone have been sufficient to make his name immortal. It cannot but disturb us very much if we find minds of the first order under suspicion of dishonesty, which would be a scandal to those of the lowest order. For we feel that theft is even more inexcusable in a rich man than in a poor one. We dare not, however, be silent; for here we are posterity, and must be just, as we hope that posterity will some day be just to us. Therefore, as a third example, I will add to these cases, that the fundamental thoughts of the "Metamorphosis of Plants," by Goethe, were already expressed by Kaspar Wolff in 1764 in his "Theory of Generation," p. 148, 229, 243, &c. Indeed, is it otherwise with the *system of gravitation*? the discovery of which is on the Continent of Europe always ascribed to Newton, while in England the learned at least know very well that it belongs to Robert Hooke, who in the year 1666, in a "Communication to the Royal Society," expounds it quite distinctly, although only as an hypothesis and without proof. The principal passage of this communication is quoted in Dugald Stewart's "Philosophy of the Human Mind," and is probably taken from Robert Hooke's Posthumous Works. The history of the matter, and how Newton got into difficulty by it, is also to be found in the "*Biographie Universelle*," article Newton. Hooke's priority is treated as an established fact in a short history of astronomy, *Quarterly Review*, August 1828. Further details on this subject are to be found in my "*Parerga*," vol. ii., § 86 (second edition, § 88). The story of the fall of an apple is a fable as groundless as it is popular, and is quite without authority.

(2) To No. 18 of Matter.

The quantity of a motion (*quantitas motus*, already in Descartes) is the product of the mass into the velocity.

This law is the basis not only of the doctrine of impact in mechanics, but also of that of equilibrium in statics. From the force of impact which two bodies with the same velocity exert the relation of their masses to each other may be determined. Thus of two hammers striking with the same velocity, the one which has the greater mass will drive the nail deeper into the wall or the post deeper into the earth. For example, a hammer weighing six pounds with a velocity = 6 effects as much as a hammer weighing three pounds with a velocity = 12, for in both cases the quantity of motion or the momentum = 36. Of two balls rolling at the same pace, the one which has the greater mass will impel a third ball at rest to a greater distance than the ball of less mass can. For the mass of the first multiplied by the same velocity gives a *greater quantity of motion*, or a *greater momentum*. The cannon carries further than the gun, because an equal velocity communicated to a much greater mass gives a much *greater quantity of motion*, which resists longer the retarding effect of gravity. For the same reason, the same arm will throw a lead bullet further than a stone one of equal magnitude, or a large stone further than quite a small one. And therefore also a case-shot does not carry so far as a ball-shot.

The same law lies at the foundation of the theory of the lever and of the balance. For here also the smaller mass, on the longer arm of the lever or beam of the balance, has a greater velocity in falling; and multiplied by this it may be equal to, or indeed exceed, the *quantity of motion* or the *momentum* of the greater mass at the shorter arm of the lever. In the state of rest brought about by *equilibrium* this velocity exists merely in intention or virtually, *potentiâ*, not *actu*; but it acts just as well as *actu*, which is very remarkable.

The following explanation will be more easily understood now that these truths have been called to mind.

The quantity of a given matter can only be estimated in general according to its force, and its force can only be known in its *expression*. Now when we are considering matter only as regards its quantity, not its quality, this expression can only be mechanical, *i.e.*, it can only consist in

motion which it imparts to other matter. For only in motion does the force of matter become, so to speak, *alive*; hence the expression *vis viva* for the manifestation of force of matter in motion. Accordingly the only measure of the quantity of a given matter is the *quantity of its motion*, or its *momentum*. In this, however, if it is given, the *quantity* of matter still appears in conjunction and amalgamated with its other factor, *velocity*. Therefore if we want to know the quantity of matter (the mass) this other factor must be eliminated. Now the velocity is known directly; for it is *S/T*. But the other factor, which remains when this is eliminated, can always be known only *relatively* in comparison with other masses, which again can only be known themselves by means of the *quantity of their motion*, or their *momentum*, thus in their combination with velocity. We must therefore compare one *quantity of motion* with the other, and then subtract the velocity from both, in order to see how much each of them owed to its mass. This is done by weighing the masses against each other, in which that *quantity of motion* is compared which, in each of the two masses, calls forth the attractive power of the earth that acts upon both only in proportion to their *quantity*. Therefore there are two kinds of weighing. Either we impart to the two masses to be compared *equal* velocity, in order to find out which of the two now *communicates* motion to the other, thus itself *has* a greater quantity of motion, which, since the velocity is the same on both sides, is to be ascribed to the other factor of the *quantity of motion* or the *momentum*, thus to the mass (common balance). Or we weigh, by investigating how much *more velocity* the one mass must receive than the other has, in order to be equal to the latter in *quantity of motion* or *momentum*, and therefore allow no more motion to be communicated to itself by the other; for then in proportion as its velocity must exceed that of the other, its mass, *i.e.*, the quantity of its matter, is less than that of the other (steelyard). This estimation of masses by weighing depends upon the favourable circumstance that the moving force, in itself, acts upon both quite equally, and each of the two is in a position to *communicate* to the other directly its surplus *quantity of motion* or *momentum*, so that it becomes visible.

The substance of these doctrines has long ago been expressed by Newton and Kant, but through the connection and the clearness of this exposition I believe I have made it more intelligible, so that that insight is possible for all which I regarded as necessary for the justification of proposition No. 18.

Second Half. The Doctrine of the Abstract Idea, or Thinking.

Chapter V.[16] On The Irrational Intellect.

It must be possible to arrive at a complete knowledge of the consciousness of the brutes, for we can construct it by abstracting certain properties of our own consciousness. On the other hand, there enters into the consciousness of the brute instinct, which is much more developed in all of them than in man, and in some of them extends to what we call mechanical instinct.

The brutes have understanding without having reason, and therefore they have knowledge of perception but no abstract knowledge. They apprehend correctly, and also grasp the immediate causal connection, in the case of the higher species even through several links of its chain, but they do not, properly speaking, *think*. For they lack *conceptions*, that is, abstract ideas. The first consequence of this, however, is the want of a proper memory, which applies even to the most sagacious of the brutes, and it is just this which constitutes the principal difference between their consciousness and that of men. Perfect intelligence depends upon the distinct consciousness of the past and of the eventual future, *as such*, and in connection with the present. The special memory which this demands is therefore an orderly, connected, and thinking retrospective recollection. This, however, is only possible by means of *general conceptions*, the assistance of which is required by what is entirely individual, in order that it may be recalled in its order and connection. For the boundless multitude of things and events of the same and similar kinds, in the course of our life, does not admit directly of a perceptible and individual recollection of each particular, for which neither the powers of the most comprehensive memory nor our time would be sufficient. Therefore all this can only be preserved by subsuming it under general conceptions, and the consequent reference to relatively few principles, by means of which we then have always at command an orderly and adequate survey of our past. We can only present to ourselves in perception particular scenes of the past, but the time that has passed since then and its content we are conscious of only in the abstract by means of conceptions of things and numbers which now represent days and years, together with their content. The memory of the brutes, on the contrary, like their whole intellect, is confined to what they *perceive*, and primarily consists merely in the fact that a recurring impression presents itself as having already been experienced, for the present perception revivifies the traces of an earlier one. Their memory is therefore always dependent upon

what is now actually present. Just on this account, however, this excites anew the sensation and the mood which the earlier phenomenon produced. Thus the dog recognises acquaintances, distinguishes friends from enemies, easily finds again the path it has once travelled, the houses it has once visited, and at the sight of a plate or a stick is at once put into the mood associated with them. All kinds of training depend upon the use of this perceptive memory and on the force of habit, which in the case of animals is specially strong. It is therefore just as different from human education as perception is from thinking. We ourselves are in certain cases, in which memory proper refuses us its service, confined to that merely perceptive recollection, and thus we can measure the difference between the two from our own experience. For example, at the sight of a person whom it appears to us we know, although we are not able to remember when or where we saw him; or again, when we visit a place where we once were in early childhood, that is, while our reason was yet undeveloped, and which we have therefore entirely forgotten, and yet feel that the present impression is one which we have already experienced. This is the nature of all the recollections of the brutes. We have only to add that in the case of the most sagacious this merely perceptive memory rises to a certain degree of *phantasy*, which again assists it, and by virtue of which, for example, the image of its absent master floats before the mind of the dog and excites a longing after him, so that when he remains away long it seeks for him everywhere. Its dreams also depend upon this phantasy. The consciousness of the brutes is accordingly a mere succession of presents, none of which, however, exist as future before they appear, nor as past after they have vanished; which is the specific difference of human consciousness. Hence the brutes have infinitely less to *suffer* than we have, because they know no other pains but those which the *present* directly brings. But the present is without extension, while the future and the past, which contain most of the causes of our suffering, are widely extended, and to their actual content there is added that which is merely possible, which opens up an unlimited field for desire and aversion. The brutes, on the contrary, undisturbed by these, enjoy quietly and peacefully each present moment, even if it is only bearable. Human beings of very limited capacity perhaps approach them in this. Further, the sufferings which belong *purely* to the present can only be physical. Indeed the brutes do not properly speaking feel death: they can only know it when it appears, and then they are already no more. Thus then

the life of the brute is a continuous present. It lives on without reflection, and exists wholly in the present; even the great majority of men live with very little reflection. Another consequence of the special nature of the intellect of the brutes, which we have explained is the perfect accordance of their consciousness with their environment. Between the brute and the external world there is nothing, but between us and the external world there is always our thought about it, which makes us often inapproachable to it, and it to us. Only in the case of children and very primitive men is this wall of partition so thin that in order to see what goes on in them we only need to see what goes on round about them. Therefore the brutes are incapable alike of purpose and dissimulation; they reserve nothing. In this respect the dog stands to the man in the same relation as a glass goblet to a metal one, and this helps greatly to endear the dog so much to us, for it affords us great pleasure to see all those inclinations and emotions which we so often conceal displayed simply and openly in him. In general, the brutes always play, as it were, with their hand exposed; and therefore we contemplate with so much pleasure their behaviour towards each other, both when they belong to the same and to different species. It is characterised by a certain stamp of innocence, in contrast to the conduct of men, which is withdrawn from the innocence of nature by the entrance of reason, and with it of prudence or deliberation. Hence human conduct has throughout the stamp of intention or deliberate purpose, the absence of which, and the consequent determination by the impulse of the moment, is the fundamental characteristic of all the action of the brutes. No brute is capable of a purpose properly so-called. To conceive and follow out a purpose is the prerogative of man, and it is a prerogative which is rich in consequences. Certainly an instinct like that of the bird of passage or the bee, still more a permanent, persistent desire, a longing like that of the dog for its absent master, may present the appearance of a purpose, with which, however, it must not be confounded. Now all this has its ultimate ground in the relation between the human and the brute intellect, which may also be thus expressed: The brutes have only *direct* knowledge, while we, in addition to this, have *indirect* knowledge; and the advantage which in many things — for example, in trigonometry and analysis, in machine work instead of hand work, &c. — indirect has over direct knowledge appears here also. Thus again we may say: The brutes have only a *single* intellect, we a *double* intellect, both perceptive and thinking, and the operation of the two often go on

independently of each other. We perceive one thing, and we think another. Often, again, they act upon each other. This way of putting the matter enables us specially to understand that natural openness and naivete of the brutes, referred to above, as contrasted with the concealment of man.

However, the law *natura non facit saltus* is not entirely suspended even with regard to the intellect of the brutes, though certainly the step from the brute to the human intelligence is the greatest which nature has made in the production of her creatures. In the most favoured individuals of the highest species of the brutes there certainly sometimes appears, always to our astonishment, a faint trace of reflection, reason, the comprehension of words, of thought, purpose, and deliberation. The most striking indications of this kind are afforded by the elephant, whose highly developed intelligence is heightened and supported by an experience of a lifetime which sometimes extends to two hundred years. He has often given unmistakable signs, recorded in well-known anecdotes, of premeditation, which, in the case of brutes, always astonishes us more than anything else. Such, for instance, is the story of the tailor on whom an elephant revenged himself for pricking him with a needle. I wish, however, to rescue from oblivion a parallel case to this, because it has the advantage of being authenticated by judicial investigation. On the 27th of August 1830 there was held at Morpeth, in England, a coroner's inquest on the keeper, Baptist Bernhard, who was killed by his elephant. It appeared from the evidence that two years before he had offended the elephant grossly, and now, without any occasion, but on a favourable opportunity, the elephant had seized him and crushed him. (See the *Spectator* and other English papers of that day.) For special information on the intelligence of brutes I recommend Leroy's excellent book, "*Sur l'Intelligence des Animaux*," *nouv. éd.* 1802.

Chapter VI. On The Doctrine of Abstract or Rational Knowledge.

The outward impression upon the senses, together with the mood which it alone awakens in us, vanishes with the presence of the thing. Therefore these two cannot of themselves constitute *experience* proper, whose teaching is to guide our conduct for the future. The image of that impression which the imagination preserves is originally weaker than the impression itself, and becomes weaker and weaker daily, until in time it disappears altogether. There is only one thing which is not subject either to the instantaneous vanishing of the impression or to the gradual disappearance of its image, and is therefore free from the power of time. This is the *conception*. In it, then, the teaching of experience must be stored up, and it alone is suited to be a safe guide to our steps in life. Therefore Seneca says rightly, "*Si vis tibi omnia subjicere, te subjice rationi*" (Ep. 37). And I add to this that the essential condition of surpassing others in actual life is that we should reflect or deliberate. Such an important tool of the intellect as the *concept* evidently cannot be identical with the *word*, this mere sound, which as an impression of sense passes with the moment, or as a phantasm of hearing dies away with time. Yet the concept is an idea, the distinct consciousness and preservation of which are bound up with the word. Hence the Greeks called word, concept, relation, thought, and reason by the name of the first, ὀ λογος. Yet the concept is perfectly different both from the word, to which it is joined, and from the perceptions, from which it has originated. It is of an entirely different nature from these impressions of the senses. Yet it is able to take up into itself all the results of perception, and give them back again unchanged and undiminished after the longest period of time; thus alone does *experience* arise. But the concept preserves, not what is perceived nor what is then felt, but only what is essential in these, in an entirely altered form, and yet as an adequate representative of them. Just as flowers cannot be preserved, but their ethereal oil, their essence, with the same smell and the same virtues, can be. The action that has been guided by correct conceptions will, in the result, coincide with the real object aimed at. We may judge of the inestimable value of conceptions, and consequently of the reason, if we glance for a moment at the infinite multitude and variety of the things and conditions that coexist and succeed each other, and

then consider that speech and writing (the signs of conceptions) are capable of affording us accurate information as to everything and every relation when and wherever it may have been; for comparatively *few* conceptions can contain and represent an infinite number of things and conditions. In our own reflection *abstraction* is a throwing off of useless baggage for the sake of more easily handling the knowledge which is to be compared, and has therefore to be turned about in all directions. We allow much that is unessential, and therefore only confusing, to fall away from the real things, and work with few but essential determinations thought in the abstract. But just because general conceptions are only formed by thinking away and leaving out existing qualities, and are therefore the emptier the more general they are, the use of this procedure is confined to the *working up* of knowledge which we have already acquired. This working up includes the drawing of conclusions from premisses contained in our knowledge. New insight, on the contrary, can only be obtained by the help of the faculty of judgment, from perception, which alone is complete and rich knowledge. Further, because the content and the extent of the concepts stand in inverse relation to each other, and thus the more is thought *under* a concept, the less is thought *in* it, concepts form a graduated series, a hierarchy, from the most special to the most general, at the lower end of which scholastic realism is almost right, and at the upper end nominalism. For the most special conception is almost the individual, thus almost real; and the most general conception, *e.g.*, being (*i.e.*, the infinitive of the copula), is scarcely anything but a word. Therefore philosophical systems which confine themselves to such very general conceptions, without going down to the real, are little more than mere juggling with words. For since all abstraction consists in thinking away, the further we push it the less we have left over. Therefore, if I read those modern philosophemes which move constantly in the widest abstractions, I am soon quite unable, in spite of all attention, to think almost anything more in connection with them; for I receive no material for thought, but am supposed to work with mere empty shells, which gives me a feeling like that which we experience when we try to throw very light bodies; the strength and also the exertion are there, but there is no object to receive them, so as to supply the other moment of motion. If any one wants to experience this let him read the writings of the disciples of Schelling, or still better of the Hegelians. *Simple conceptions* would necessarily be such as could not be broken up. Accordingly they

could never be the subject of an analytical judgment. This I hold to be impossible, for if we think a conception we must also be able to give its content. What are commonly adduced as examples of simple conceptions are really not conceptions at all, but partly mere sensations — as, for instance, those of some special colour; partly the forms of perception which are known to us *a priori*, thus properly the ultimate elements of *perceptive knowledge*. But this itself is for the whole system of our thought what granite is for geology, the ultimate firm basis which supports all, and beyond which we cannot go. The *distinctness* of a conception demands not only that we should be able to separate its predicates, but also that we should be able to analyse these even if they are abstractions, and so on until we reach knowledge of *perception*, and thus refer to concrete things through the distinct perception of which the final abstractions are verified and reality guaranteed to them, as well as to all the higher abstractions which rest upon them. Therefore the ordinary explanation that the conception is distinct as soon as we can give its predicates is not sufficient. For the separating of these predicates may lead perhaps to more conceptions; and so on again without there being that ultimate basis of perceptions which imparts reality to all those conceptions. Take, for example, the conception "spirit," and analyse it into its predicates: "A thinking, willing, immaterial, simple, indestructible being that does not occupy space." Nothing is yet distinctly thought about it, because the elements of these conceptions cannot be verified by means of perceptions, for a thinking being without a brain is like a digesting being without a stomach. Only perceptions are, properly speaking, *clear*, not conceptions; these at the most can only be distinct. Hence also, absurd as it was, "clear and confused" were coupled together and used as synonymous when knowledge of perception was explained as merely a confused abstract knowledge, because the latter kind of knowledge alone was distinct. This was first done by Duns Scotus, but Leibnitz has substantially the same view, upon which his "*Identitas Indiscernibilium*" depends. (See Kant's refutation of this, p. 275 of the first edition of the Critique of Pure Reason.)

The close connection of the conception with the word, thus of speech with reason, which was touched on above, rests ultimately upon the following ground. *Time* is throughout the form of our whole consciousness, with its inward and outward apprehension. Conceptions, on the other hand, which originate through abstraction and are perfectly general ideas,

different from all particular things, have in this property indeed a certain measure of objective existence, which does not, however, belong to any series of events in time. Therefore in order to enter the immediate present of an individual consciousness, and thus to admit of being introduced into a series of events in time, they must to a certain extent be reduced again to the nature of individual things, individualised, and therefore linked to an idea of sense. Such an idea is the *word*. It is accordingly the sensible sign of the conception, and as such the necessary means of *fixing* it, that is, of presenting it to the consciousness, which is bound up with the form of time, and thus establishing a connection between the reason, whose objects are merely general universals, knowing neither place nor time, and consciousness, which is bound up with time, is sensuous, and so far purely animal. Only by this means is the reproduction at pleasure, thus the recollection and preservation, of conceptions possible and open to us; and only by means of this, again, are the operations which are undertaken with conceptions possible — judgment, inference, comparison, limitation, &c. It is true it sometimes happens that conceptions occupy consciousness without their signs, as when we run through a train of reasoning so rapidly that we could not think the words in the time. But such cases are exceptions, which presuppose great exercise of the reason, which it could only have obtained by means of language. How much the use of reason is bound up with speech we see in the case of the deaf and dumb, who, if they have learnt no kind of language, show scarcely more intelligence than the ourang-outang or the elephant. For their reason is almost entirely potential, not actual.

Words and speech are thus the indispensable means of distinct thought. But as every means, every machine, at once burdens and hinders, so also does language; for it forces the fluid and modifiable thoughts, with their infinitely fine distinctions of difference, into certain rigid, permanent forms, and thus in fixing also fetters them. This hindrance is to some extent got rid of by learning several languages. For in these the thought is poured from one mould into another, and somewhat alters its form in each, so that it becomes more and more freed from all form and clothing, and thus its own proper nature comes more distinctly into consciousness, and it recovers again its original capacity for modification. The ancient languages render this service very much better than the modern, because, on account of their great difference from the latter, the same thoughts are expressed in them in quite another way, and must thus assume a very different form; besides

which the more perfect grammar of the ancient languages renders a more artistic and more perfect construction of the thoughts and their connection possible. Thus a Greek or a Roman might perhaps content himself with his own language, but he who understands nothing but some single modern patois will soon betray this poverty in writing and speaking; for his thoughts, firmly bound to such narrow stereotyped forms, must appear awkward and monotonous. Genius certainly makes up for this as for everything else, for example in Shakespeare.

Burke, in his "Inquiry into the Sublime and Beautiful," p. 5, § 4 and 5, has given a perfectly correct and very elaborate exposition of what I laid down in § 9 of the first volume, that the words of a speech are perfectly understood without calling up ideas of perception, pictures in our heads. But he draws from this the entirely false conclusion that we hear, apprehend, and make use of words without connecting with them any idea whatever; whereas he ought to have drawn the conclusion that all ideas are not perceptible images, but that precisely those ideas which must be expressed by means of words are abstract notions or conceptions, and these from their very nature are not perceptible. Just because words impart only general conceptions, which are perfectly different from ideas of perception, when, for example, an event is recounted all the hearers will receive the same conceptions; but if afterwards they wish to make the incident clear to themselves, each of them will call up in his imagination a different *image* of it, which differs considerably from the correct image that is possessed only by the eye-witness. This is the primary reason (which, however, is accompanied by others) why every fact is necessarily distorted by being repeatedly told. The second recounter communicates conceptions which he has abstracted from the image of *his own* imagination, and from these conceptions the third now forms another image differing still more widely from the truth, and this again he translates into conceptions, and so the process goes on. Whoever is sufficiently matter of fact to stick to the conceptions imparted to him, and repeat them, will prove the most truthful reporter.

The best and most intelligent exposition of the essence and nature of conceptions which I have been able to find is in Thomas Reid's "Essays on the Powers of Human Mind," vol. ii., Essay 5, ch. 6. This was afterwards condemned by Dugald Stewart in his "Philosophy of the Human Mind." Not to waste paper I will only briefly remark with regard to the latter that he

belongs to that large class who have obtained an undeserved reputation through favour and friends, and therefore I can only advise that not an hour should be wasted over the scribbling of this shallow writer.

The princely scholastic Pico de Mirandula already saw that reason is the faculty of abstract ideas, and understanding the faculty of ideas of perception. For in his book, "*De Imaginatione*," ch. 11, he carefully distinguishes understanding and reason, and explains the latter as the discursive faculty peculiar to man, and the former as the intuitive faculty, allied to the kind of knowledge which is proper to the angels, and indeed to God. Spinoza also characterises reason quite correctly as the faculty of framing general conceptions (Eth., ii. prop. 40, schol. 2). Such facts would not need to be mentioned if it were not for the tricks that have been played in the last fifty years by the whole of the philosophasters of Germany with the conception *reason*. For they have tried, with shameless audacity, to smuggle in under this name an entirely spurious faculty of immediate, metaphysical, so-called super-sensuous knowledge. The reason proper, on the other hand, they call *understanding*, and the understanding proper, as something quite strange to them, they overlook altogether, and ascribe its intuitive functions to sensibility.

In the case of all things in this world new drawbacks or disadvantages cleave to every source of aid, to every gain, to every advantage; and thus reason also, which gives to man such great advantages over the brutes, carries with it its special disadvantages, and opens for him paths of error into which the brutes can never stray. Through it a new species of motives, to which the brute is not accessible, obtains power over his will. These are the *abstract* motives, the mere thoughts, which are by no means always drawn from his own experience, but often come to him only through the talk and example of others, through tradition and literature. Having become accessible to thought, he is at once exposed to error. But every error must sooner or later do harm, and the greater the error the greater the harm it will do. The individual error must be atoned for by him who cherishes it, and often he has to pay dearly for it. And the same thing holds good on a large scale of the common errors of whole nations. Therefore it cannot too often be repeated that every error wherever we meet it, is to be pursued and rooted out as an enemy of mankind, and that there can be no such thing as privileged or sanctioned error. The thinker ought to attack it, even if humanity should cry out with pain, like a sick man whose ulcer the

physician touches. The brute can never stray far from the path of nature; for its motives lie only in the world of perception, where only the possible, indeed only the actual, finds room. On the other hand, all that is only imaginable, and therefore also the false, the impossible, the absurd, and senseless, enters into abstract conceptions, into thoughts and words. Since now all partake of reason, but few of judgment, the consequence is that man is exposed to delusion, for he is abandoned to every conceivable chimera which any one talks him into, and which, acting on his will as a motive, may influence him to perversities and follies of every kind, to the most unheard-of extravagances, and also to actions most contrary to his animal nature. True culture, in which knowledge and judgment go hand in hand, can only be brought to bear on a few; and still fewer are capable of receiving it. For the great mass of men a kind of training everywhere takes its place. It is effected by example, custom, and the very early and firm impression of certain conceptions, before any experience, understanding, or judgment were there to disturb the work. Thus thoughts are implanted, which afterward cling as firmly, and are as incapable of being shaken by any instruction as if they were *inborn*; and indeed they have often been regarded, even by philosophers, as such. In this way we can, with the same trouble, imbue men with what is right and rational, or with what is most absurd. For example, we can accustom them to approach this or that idol with holy dread, and at the mention of its name to prostrate in the dust not only their bodies but their whole spirit; to sacrifice their property and their lives willingly to words, to names, to the defence of the strangest whims; to attach arbitrarily the greatest honour or the deepest disgrace to this or that, and to prize highly or disdain everything accordingly with full inward conviction; to renounce all animal food, as in Hindustan, or to devour still warm and quivering pieces, cut from the living animal, as in Abyssinia; to eat men, as in New Zealand, or to sacrifice their children to Moloch; to castrate themselves, to fling themselves voluntarily on the funeral piles of the dead — in a word, to do anything we please. Hence the Crusades, the extravagances of fanatical sects; hence Chiliasts and Flagellants, persecutions, *autos da fe*, and all that is offered by the long register of human perversities. Lest it should be thought that only the dark ages afford such examples, I shall add a couple of more modern instances. In the year 1818 there went from Würtemberg 7000 Chiliasts to the neighbourhood of Ararat, because the new kingdom of God, specially announced by Jung

Stilling, was to appear there.[17] Gall relates that in his time a mother killed her child and roasted it in order to cure her husband's rheumatism with its fat.[18] The tragical side of error lies in the practical, the comical is reserved for the theoretical. For example, if we could firmly persuade three men that the sun is not the cause of daylight, we might hope to see it soon established as the general conviction. In Germany it was possible to proclaim as the greatest philosopher of all ages Hegel, a repulsive, mindless charlatan, an unparalleled scribbler of nonsense, and for twenty years many thousands have believed it stubbornly and firmly; and indeed, outside Germany, the Danish Academy entered the lists against myself for his fame, and sought to have him regarded as a *summus philosophus*. (Upon this see the preface to my *Grundproblemen der Ethik*.) These, then, are the disadvantages which, on account of the rarity of judgment, attach to the existence of reason. We must add to them the possibility of madness. The brutes do not go mad, although the carnivora are subject to fury, and the ruminants to a sort of delirium.

Chapter VII.[19] On The Relation of the Concrete Knowledge of Perception to Abstract Knowledge.
